P334

INDEX

ABABEI, L , et *al* Effect of Molybdenum and Tungsten Ions on Intermediate Metabolism of Glutamine in Rat Liver and Brain, 470
Abdel-Malek, Prof A A Inhibitory Effect of L-Methionine-methyl-^{14}C on Oviposition by Females of the Cotton Leaf Worm *Prodenia litura* (F) induced by Radioactive Males, 604
Abnormal Glucose Tolerance in Repeatedly Bred Rats with Arteriosclerosis (Prof B C Wexler and Dr C T Fischer), 133
Abnormally Divergent 'Sectors' in Cultures of Filamentous Fungi (Prof P K Isaac,) 382
Aboriginal Cultural Development in Latin America, 217
Abrahams, C , et *al* Phenacetin-induced Papillary Damage in Experimental Animals, 695
Abscission in Explants of *Phaseolus vulgaris* Effect of Kinetin on Senescence and (D J Osborne and S E Moss), 1299
Absence of Lysolecithin Formation in C_3-deficient Rabbit Serum (I Haupt, Prof H Fischer, U Rother and K Rother), 686
Absence of Ribonuclease from the Ribosomes of *Pseudomonas fluorescens* (H E Wade and H K Robinson), 661
Absorption in Radio Sources of High Brightness Temperature (P J S Williams), 56
Abstract Harmonic Analysis (Prof Edwin Hewitt and Prof Kenneth A Ross), Vol I, *review* by Dr T A S Jackson, 1253
Academic and Industrial Contributions to Drug Research (Prof Ernst B Chain) Lecture given at the Royal Society of Arts, June 1963, 441
Academy of Sciences The Prix Jecker Awarded, 1264
Acceleration of Sinking Rates of Radionuclides in the Ocean (Prof C Osterberg, Dr A G Carey, jun , and Dr H Curl, jun), 1276
Accumulation of Oxytetracycline Relevant to its Bactericidal Action in the Cells of *Escherichia coli* (K Arima and K Izaki), 192
Acetal Radiation-induced Hydrolysis of (D R Smith and W H Stevens), 66
Acetylcholine Excitation of Cerebellar Neurones by (Dr J M Crawford et *al*), 579
Acetylcholine in the Rat's Brain Effect of 'Tremorine' and some Anti-Parkinson's Disease Drugs on (Dr G Pepeu), 895
Acetylcholine-releasing Material in Neural Tissues (Prof J P Green, Dr E A Carlini and J D Robinson), 1108
Acetylcholinesterase Inactivation of Enzyme-treated Erythrocytes (Dr F Herz, E Kaplan and J H Stevenson, jun), 901
Acetylene from Coal, using a Plasma Jet Production of (R L Bond et *al*), 1313
Acetylsalicyclic Acid on the Body-temperature of Heat-stressed Chickens Influence of (Prof B Glick), 603
Acetylsalicylate in Guinea Pig Lung Anti-anaphylactic Action of (H O J Collier et *al*), 176 , *erratum*, 525
Acha, I G , et *al* Proteolytic Activity of Growth Media Filtrates from Non-pathogenic Species of *Verticillium*, 290
Acha, G , and Villanueva, Dr J R Differences in the Mode of Action of Strepzyme and *Helix pomatia* Enzyme Preparations on *Trichotecium roseum* Spores, 1231
Acid-buffered Acetone as a Fixative for Enzyme Cytochemistry (Dr L S Kaplow and Dr M S Burstone), 690
α_1-Acid Glycoprotein Variants of (Dr K Tokita and Dr K Schmid,) 266
Acid Mucopolysaccharide Content of Dermal Connective Tissue of Normal and Hypophysectomized Rats (Go Matsumura, J Fabianek, A Herp and W Pigman), 784
Acidic Polysaccharide Antigens of a New Type from *E coli* Capsules (I Ørskov, F Ørskov, B Jann and K Jann), 144
Ackman, Dr R G , et *al* Quantitative Gas-Liquid Chromatography of the Higher Fatty Acids, 777
Acriflavine Effects on Irradiated Micro-organisms of Growth in the Presence of (T Alper), 534
Actinomycin *D* of Latent Period of Multiplication of Sendai Virus Shortening by (A G Bukrinskaya and V M Zhdanov), 920
Actinomycin *D* on Interferon Production by 'Active' and 'Inactive' Chikungunya Virus in Chick Cells Effect of (Dr G E Gifford and Dr E Heller), 50
Action of Bovine and Human Pancreatic Phospholipase *A* on Lipoprotein-bound Phospholipids (E Condrea, C Klibansky, R Keret and Prof A de Vries, 1096
Action of 5-Bromo-3-sec-butyl-6-methyluracil on *Escherichia coli* 15T (Dr J W McGahen and Dr C E Hoffman), 571
Action Current as a Possible Source for the Negative After-Potential of Striated Muscle (Prof H Jenerick), 1076
Action of Piperazine on the Neuromuscular System of *Ascaris lumbricoides* (Prof J del Castillo, T A Morales and V Sanchez), 706
Action of Polar Reagents on Nylon 66 (G Sarda and Dr N Peacock), 67
Action of Prostaglandin E_1 on Tissues which respond to Bradykinin (Dr E W Horton), 892
Action of Puffer Fish Poison (K M Li), 791
Action of Tumour Growth and Tissue Products on the Zonal Distribution of Liver Glycogen in Rats and Mice (Dr J P Guimaraes and M C Santos Motta), 84
Activation Analysis in Medicine and Biochemistry (Dr J M A Lenihan),, 637
Active Dark Filaments and Type III Bursts (A Tlamicha and T Takakura), 999
Active Immunization of a Human Being Against (*Naja naja*) Venom (Capt H H Flowers), 1017
Active Transport and Transfer of Energy (Dr N R Ghosh), 175
Actomyosin Third Component Participating in the Superprecipitation of Natural (Prof S Ebashi), 1010
Adam, N K Interfacial Phenomena, second edition, *review*, 1140
Adamec, V Dielectric Loss Factor of Polytetrafluoroethylene under Irradiation, 1196
Adams, Dr R D , and Randall, M J Observed Triplication of *PKP*, 744
Adams, S S , et *al* Some Biological Properties of 'Ibufenac', a New Antirheumatic Drug, 271
Adams Smith, W N Influence of Trypan Blue on Resorption of Rat Embryos, 699
Additive Effect of Sub-threshold Concentrations of some Organic Compounds Associated with Food Aromas (D G Guadagni, R G Buttery, S Okano and H K Burr), 1288
Adenosine in Various Morphological Forms Photoconduction of (C Y Liang and E G Scalco), 1319
Adenosine of the Effect of Adenosine Diphosphate on the Concentration of Circulating Platelets Prevention by (Dr D Regoli and V Clark), 546
Adenosine Triphosphatase in Normal and Scorbutic Wounds (Dr R L Cabrini and Dr F A Carranza, jun), 1113
Adenosine Triphosphatase in Schizophrenic Erythrocytes Sodium-Potassium-activated (Dr P M Seeman and E O'Brien), 263
Adenosine Triphosphatase or Sarcoplasmic Reticulum Triads and Sarcolemma identified histochemically (Dr W King Engel), 588
Adenosine Triphosphate Anticoagulant Action of (Dr A J Quick), 469
Adenosine Triphosphate-dependent Reduction of Nicotinamide Adenine Dinucleotide by Ferrocytochrome c in Chemoautotrophic Bacteria (Dr M I H Aleem, Dr H Lees and Dr D J D Nicholas), 759
Adenosine Triphosphate Generated from Phytate Complete Intracellular Unit for Incorporation of Amino-acid into Storage Protein Utilizing (the late Prof R K Morton and J K Raison), 429
Adhesion Particle Size Classification by (J H Burson et *al*), 360
Adie, P A , et *al* Increased Concentrations of Blood Lipids in Guinea Pigs poisoned by Sarin, 897
Adjuvants Protective Effect of Killed Trypanosome Vaccines with Incorporated (P Johrson et *al*), 83
"Administration and Management of Research and Development", course in, 120
Administration of Education and Civil Science in Britain, 1245
Admiralty Hydrographic Department Admiralty Marine Science Publications, No 6 *Hydrographic Analysis of the Sandbanks in the Approaches to Lowestoft Harbour*, 1275
Adrenal Cortex of the Rat Influence of Adrenocorticotrophic Hormone, Hydrocortisone and Hypophysectomy on the Distribution of β-Glucuronidase in the (Dr G Th A M Bots et *al*), 1111
Adrenaline and Anti-Adrenaline Compounds on Platelets *in vitro* and *in vivo* Some Effects of (Dr J R O'Brien), 763
Adrenocortical Steroids 'Sephadex' Gel Filtration as a Method of Purification of Urinary (D Gupta), 574
Adrenocorticotrophic Hormone, Hydrocortisone and Hypophysectomy on the Distribution of β-Glucuronidase in the Adrenal Cortex of the Rat Influence of, (Dr G Th A M Bots et *al*), 1111
Advances in Biological and Medical Physics, Vol 8 (edited by Cornelius A Tobias and John H Lawrence), *review* by Dr N M Blackett, 973
Advances in Cancer Research, Vol 7 (edited by Prof Alexander Haddow and Sidney Weinhouse), *review* by Dr W J P Neish, 980
Advances in Enzymology and Related Subjects of Biochemistry, Vol 24 (edited by F F Nord), *review* by Dr T Mann, 972
Advances in Insect Physiology, Vol I (edited by J W L Beament, J E Treherne and V B Wigglesworth), *review* by Prof J W S Pringle, 507
Advances in Parasitology, Vol I (edited by Dr Ben Dawes), *review* by Dr G Lapage, 103
Advances in Programming and Non-numerical Analysis (D Michie), 641
Advances in Virus Research Vol 9 (edited by Kenneth M Smith and Max A Lauffer), *review* by N W Pirie, 620
Advisory Council on Scientific Policy, 1962–1963, Sixteenth Annual Report (Cmnd 2163), 1133 ,
  Committee on Scientific Manpower *Scientific and Technological Manpower in Great Britain*, 1962 (Cmnd 2146), 297, 1133
Aerobic Conditions Synthesis of Bacteriochlorophyll by *Rhodopseudomonas spheroides* under Dark (M Higuchi and G Kikuchi), 1191
Affinity of Andamanese recent Stone Industry (P C Dutta), 997
Aflatoxins Toxicity and Fluorescence Properties of the (R B A Carnaghan et *al*), 1101
After-image Phenomenon Effects of Field Brightness on an Induced Negative (Prof M H Keeler), 194
Agar Layer Bacteriophage Plaque-count Assay and Confluent Lysis on Plates without Bottom (S Rizvi and Dr P T Mora), 1324
Age and Significance of Diabase Dyke Swarms of the Canadian Shield (W F Fahrig and R K Wanless), 934
Age Differences in Choice Reaction Time and Cardiovascular Status among Pilots (Dr J Szafran), 904
Age of the Great Dyke of Southern Rhodesia (Prof G Faure, Dr P M Hurley, Prof H W Fairbairn and Prof W H Pinson, jun), 769
Age of the North American Crust (Dr W F Slawson, Dr E R Kanasewich, Dr R G Ostic and Prof R M Farquhar), 413
Age Resistance by Turkeys to *Eimeria meleagrimitis* Tyzzer, 1929 (E W Warren, S J Ball and J R Fagg), 238
'Ageing' of Silica Suspensions in Water and its Influence on Flocculation by Polyacrylamide (Dr O Griot and Dr J A Kitchener), 1004
Ager, Derek V Principles of Paleoecology, *review* by Dr G Y Craig, 1035
Ager, Dr D V , and Nicholas, Dr D Marine Ecology and Palæoecology, 942
Aggregation of Cultured Mammalian Cells (Prof M Moskowitz), 854
Aggregation of Protein Particles in Tumour Cells (A Bolognari, M P Albanese and A Donato), 809
Agricultural Biochemistry Prof D J D Nicholas appointed to the chair of, 406
Agricultural Research Council Memoirs of the Soil Survey of Great Britain–England and Wales *The Soils and Land Use of the District Around Bangor and Beaumaris*), 1055
  Nutrient Requirements of Farm Livestock, (No I *Poultry–Summary of Recommendations*), 1154
  Radiobiological Laboratory, Wantage, annual report 1962–63, (ARCRL 10), 633
Aid to Developing Countries, H M Treasury (Cmnd 2137), 1053

INDEX

Air Sedimentation of a Large Number of Particles as a Cluster in (Dr G W. Slack), 1306
Air Layers in Tubes Light Emission from Shock-front Compressed (Prof C. H Johansson and T Sjolin), 352
Aisenberg, Dr A C Suppression of Immune Response by 'Vincristine' and 'Vinblastine', 484
Aiya, Prof S V C, and Sonde, B S Number of Cells developed during the Life-time of a Thunderstorm, 562
Ajmaline, Pharmacological Action of (Prof M L Chatterjee and M S De), 1067
Åkerfeldt, Dr S Hydrolysis of the Phosphorothioate Ion catalysed by Silicone Grease, 881
Akiyama, M and Ito, R A Hæmagglutination Phenomenon between Tanned Erythrocytes and Sera of Guinea Pigs, 791
Albanese, M P, *et al* Aggregation of Protein Particles in Tumour Cells, 809
Albar Resistance to Bacterial Blight of Cotton in (N L Innes), 387
Alcohol and Evoked Potentials in the Cat (Dr A R Dravid, Dr R Di Perri, Dr A Morillo and Dr H E Himwich), 1328
Aldolase Limiting Factor in the Assay of (Dr B Dalos), 1013
Aldolase in Primary Liver Cancer Anomaly of (F Schapira et *al*), 995
Aldosterone by Rat Tissues Uptake of Tritiated (L L Sulya et *al*), 788
Aldosterone on the Bladder of the Toad Site of Action of (Dr J Crabbé), 787
Aldred, C *Obituary* of Dr W C Hayes, 1048
Aleem, Dr M I H, et *al* Adenosine Triphosphate-dependent Reduction of Nicotinamide Adenine Dinucleotide by Ferrocytochrome c in Chemoautotrophic Bacteria, 759
Alexander, Dr J M Appointed Professor of Engineering Plasticity, 317
Alexander, Dr P, et *al* Progress of Cancer Research, 1043
Alexander, Dr R McN Frontal Foramina and Tripodes of the Characin *Crenuchus*, 1225
Alexander, W Electrical Instruments and Measurements, second edition, *review* by Prof A H M Arnold, 987
Alfred, Dr L J, et *al* Formation of Antibody in Tissue Culture Effect of Certain Mucopolysaccharides and Hexosamine, 698
Algæ Gibberellin-like Substances in (J A Mowat), 453
  Liberation of Extracellular Nitrogen by Two Nitrogen-fixing Blue-green (Dr W D P Stewart), 1020
Algal Growths Natural Occurrence of Amino-acids in Dolomitic Limestones containing (Dr J S Harington and Dr P D Toens), 947
Algen Beiträge zur Physiologie und Morphologie der, *review* by Dr A Allsopp, 508
Alha, A, et *al* Cæsium-137 in the Blood of the Finnish Lapps, 1119
Alkali and Yield of Ribonucleic Acid from Plant-leaf Tissue Relation between the Length of Exposure to (Prof D F Millikan and E E Pickett), 470
Alkaline Degradation of Cystine, Glutathione and Sulphur-containing Proteins (Dr F M Robbins and Dr J A Fioriti), 577
Alkaline Phosphatase Heterogeneity of Human Intestinal (Dr D W Moss), 1206
Alkaline Phosphatases in Brain and Spinal Cord (Dr K Nandy and Prof G H Bourne), 1216
Allan, I R H, and Bulleid, M J Long-distance Migration of Atlantic Salmon, 89
Allelism of Silver, Gold and Imperfect Albinism in the Fowl (Prof R K Cole and T K Jeffers), 1238
Allen, Dr C The Biology of Mental Defect, third edition, *review*, 1139
Allen, Dr C R Appointed lecturer in Chemistry, 941
Allen, Dr J M V, and Reif, Prof A E Specificity of Isoantisera against Leukæmic and Thymic Lymphocytes, 1332
Allen, J R L Internal Sedimentation Structure of Well-washed Sands and Sandstones in Relation to Flow Conditions, 326
Allen, Dr M Delia Infectious Diseases of the Honey-Bee, *review*, 990
Allergy Research Recent Advances in (edited by F Hahn *et al*), 1038
Allibone, Dr T E Nuclear Instruments and Their Uses, Vol 1, *review*, 1136
  Proceedings of the Symposium on Nuclear Instruments, Harwell, September 1961, *review*, 1136
  The Collected Papers of Enrico Fermi, Vol 1, *review*, 961
  Obituary of D P R Petrie, 733
Allis, Prof William P, et *al* Waves in Anisotropic Plasmas, *review* by E G Broadbent, 821
Allison, Dr A C, and Mason, R. · Quantum Biochemistry, *review*, 1037
Allison, J C S, and Vernon, A J A Method of Calculating Net Assimilation Rate, 814
Allopreening in the Red Avadavat and its Development in Other Birds Significance of (J H Sparks), 281
Allotype, An Alpha-globulin, in the Mouse (*MuBl*), (Prof B Cinader and S Dubiski), 781
Allsopp, Dr A Beiträge zur Physiologie und Morphologie der Algen, *review*, 508
  Moderne Methoden der Pflanzenanalyse, Band 6, *review*, 618
Alper, T Effects on Irradiated Micro-organisms of Growth in the Presence of Acriflavine, 534
Alpers, H S, and Shore, Prof P A Platelet Damage Induced in Plasma by Certain Fatty Acids, 1331
Alpha-methyl *Meta*-tyrosine Behavioural Stimulation due to (P L Carlton), 586
Aluminium X-ray Emission Spectroscopic Investigation of Sealing of Anodic Oxide Films on (Dr R C Spooner and W J Forsyth), 1002
Aluminium Ions by X-ray Emission Spectroscopy Determining the Co-ordination Number of (D E Day), 649
Aluminium-Magnesium Alloys Enhanced Age-hardening in (I J Polmear and K R Sargant), 669
Amaldi, E, et *al* (edited by) The Collected Papers of Enrico Fermi, Vol 1, *review* by Dr T E Allibone, 961
Ambassade de France, Service de Presse et d'Information · *The French Budget and Finance Act for* 1963, 523 , *Some Aspects of Scientific Research in France*, 523
American Academy of Arts and Sciences, Records of the, 1962-63, 940
American Association for the Advancement of Science, Annual Meeting, 737
American Geographical Society Elections, 836
American Geophysical Union Third Western National Meeting 1963, 218
American Institute of Physics Handbook (edited by Dr Dwight E Gray), second edition, *review* by Prof S Tolansky, 963
American Society for the Study of Sterility, Awards to be made 1964, 1155
Amiel, J L, and Mathe, Dr G Comparison of the Sensitivity to Storage at 37°C in Tyrode Solution of Immunologically Competent Cells and of Myeloid Cells, 1224
Amine-Alcohol Systems Hydrogen Bonding in Gaseous Mixtures (S G W Ginn and Dr J L Wood), 467
Amines Quaternized Sympathomimetic (Prof J H Burn *et al*), 270
Amines in the Hypothalamus A New Concept of Temperature Regulation by (Dr W Feldberg and R D Myers), 1325
Amino-acid Accumulation by Kidney Cortex Slices . *In vitro* Effect of Salicylate on (Dr S Segal and A Blair), 139
Amino-acid Balance Control of Egg Size in Chickens through Dietary (B E March and Prof J Biely), 702
Amino-acid Configuration of Mycobacillin (A. B. Banerjee and Dr. S K. Bose), 471
Amino-acid into Storage Protein Utilizing Adenosine Triphosphate Generated from Phytate Complete Intracellular Unit for Incorporation of (the late Prof R K Morton and J K Raison), 429
Amino-acid Level in the Cells of *Bacillus megatherium* Independence of the Formation of Extracellular Protease on the (Dr J Chaloupka *et al*), 885
Amino-acid Sequences within the Ferrichrome Cyclic Hexapeptides (Dr S J. Rogers, Dr R A J Warren and Prof J B Neilands), 167
Amino-acids Stability of *N*-Glycuronyl (S M Amir et *al*), 166
Amino-acids and Protein on Food Intake in Hyperphagic Rats 'Safety Valve' Effect of Excess Dietary (R M Krauss and Prof J Mayer), 1213
Amino-acids as Ice Nucleators Anomalous Behaviour of some (N Barthakur and Dr J Maybank), 866
α-Amino-acids by the Strecker Synthesis Asymmetric Synthesis of (Dr K Harada), 1201
Amino-acids in Dolomitic Limestones containing Algal Growths Natural Occurrence of (Dr J S Harington and Dr P D Toens), 947
D-Amino-acids to stimulate Antibody Formation Apparent Inability of Polypeptides constructed from (Dr G Zubay), 483
α-Amino-isobutyric Acid Transport in the Absence of Protein Synthesis *In vitro* Stimulation by Insulin of (Dr G R Fritz and Prof E Knobil), 682
6-Aminonicotinamide and the Radiosensitivity of Human Liver Cells in Culture . (Dr D L Dewey and Christine Hawes), 1176
6-Aminopenicillanic Acid by Dermatophytes Production of (Dr J Uri et *al*), 896
Amir, S M, et *al* Stability of *N*-Glycuronyl Amino-acids, 166
Ammonium Molybdophosphate as Scavenger Gamma-ray Spectrometric Determination of Cæsium-137 in Sea-water by using (Dr N Yamagata), 157
Amphetamine Excitatory Response in Reserpinized Rats Effects of *α*-Methyl DOPA and DOPA on the (R M Quinton and G Halliwell), 178
Amphibian Lung Lining in Bird, Reptile and (R E Pattle and D A W Hopkinson), 894
Amphibian Carotid Labyrinth Distinctive Cell Types in the (D C Rogers), 492
Amphotericin *B* in the Chemotherapy of Experimental *Schistosomiasis mansoni* in Swiss Mice (B L Gordon and Philip A St John), 790
Amsterdam, D, and Cohen, Dr L A Immunological Identification of a Rivanol 'Purified' Fraction of Macrocryoglobulinæmia (Waldenstrom) Serum, 341
Amygdala and on the Hyper-irritability of the 'Septal Rat' A New Chemical Structure with Specific Depressant Effects on the (Dr. Z P Horovitz et *al*), 369
Amylase Electrophoretic Behaviour of Rabbit Serum (Prof J E Berk et *al*), 572
Anacardic Acids of Varying Unsaturation *Surface-active Characteristics of Sodium* Salts of (A K Biswas and A B Ray), 1203
Anacystis nidulans Distribution of Carbon-14 in Polysaccharide after Photosynthesis in Carbon Dioxide labelled with Carbon-14 by (P Kindel and Prof M Gibbs), 260
Anæmic Stress Changes in the Concentration of Potassium in the Erythrocytes and in Hæmoglobin Type in Merino Sheep under a Severe (Dr M H Blunt and Prof J V Evans), 1215
Anaerobic Life in a Tropical Crater Lake (Prof L C Beadle), 1223
Anaerobic Production of *α*-Glycerolphosphate by Cell-free Preparations of Rat Hepatomas and the Effect of Potassium Cyanide (Dr P Emmelot and C J Bos), 364
Anaerobiosis Apple Scald Induction by (Dr D R Dilley et *al*), 1229
Anæsthetic Chemical Potential *in vivo* A Probe for Continuous Determination of (Dr J A Parsons), 1286
Analysis of *A* and *B* Wave Interaction in the Rabbit Retina (Dr E L Pautler and Dr R A Wilson), 1212
Analysis of Spray-drop Data (K I. Williamson and W B Taylor), 813
Analytical Chemistry 1962 Proceedings of the International Symposium held at Birmingham University, 1962, in Honour of Fritz Feigl to Commemorate his 70th Birthday (edited by Philip W West, A M G MacDonald and T S West), *review* by Dr R Wood, 988
"Analytical Chemistry and Applied Spectroscopy", fifteenth conference on, 409
Analytical Methods for Pesticides, Plant Growth Regulators and Food Additives (edited by Gunter Zweig), Vol 1, *review* by Dr M Pyke, 971
Anbar, Prof M Possible Role of Copper Ions in Radiobiological Damage, 376
Andamanese Recent Stone Industry Affinity of (P C Dutta), 997
Andersen, Dr P, *et al* Strychnine-resistant Central Inhibition, 843
Andersen, P, and Klewe, B X-ray Investigation of Potassium Tricyanomethanide ($KC(CN)_3$), 464
Andersen, T Annealing by Compression following Chemical Radiation Damage in Potassium Bromate, 1094
Anderson, B W Proceedings of the First International Congress on Diamonds in Industry, *review*, 3
Anderson, G, et *al* Rapid Method for Determining Phytase Activity of Soil Micro-organisms, 1231
Anderson, H J, *et al* Ultra-violet Photolysis of Unsaturated Fatty Acids in Relation to the Thiobarbituric Acid Test, 1098
Anderson, Dr J Edward Magnetohydrodynamic Shock Waves, *review* by E G Broadbent, 821
Anderson, N A, and Woodruff, Prof M F A Effect of Lymphocyte Depletion by Thoracic Duct Fistula and Administration of Antilymphocytic Serum on the Survival of Skin Homografts in Rats, 702
Anderson, Dr P J, *et al* Orthogonal Diameters in the Analysis of Muscle Fibre Size and Form, 1220
Anderson, Paul J, and Barka, Tibor Histochemistry Theory, Practice and Bibliography, *review* by Prof G J Cunningham, 619
Anderson, P L, et *al* Small-angle Scattering by Pyrolytic Graphic, 555
Anderson-Berry, David, Silver-Gilt Medal, 737
Anderton, J I Pathogenic Organisms in Relation to Pasteurized Cured Meats, *review* by D Pearson, 991
Anderton, Pamela, and Bigg, P H The Yard Unit of length, 730
Andriese, P C, et *al* Gaseous-ion-induced Stimulation of Cytochrome *c* Biosynthesis, 707
Andromeda Galaxy Distance of the (*Astronomical J*, 68, 435 , 1963), 736
Anencephalic and Spina Bifida Sibships with Two Affected Cases Random Distribution of Affected Birth Ranks in (Dr S Milham, jun), 480
Anguilla anguilla and *Conger conger* Histochemical Reaction for Steroid-3β-ol-dehydrogenase in the Interrenal and Corpuscles of Stannius of (Prof G Chieffi and V Botte), 793
Angus, Dr W R Identification of Molecular Spectra, third edition, *review*, 205
Animal Biology and the Medical Sciences Use of, Vol 1 Proceedings of a Conference held in Mexico City, 1961, *review* by Dr K E Halnan, 203
Animal Health Yearbook, 1962 (FAO-WHO-OIE), *review* by W A Pool, 301
Animal Organisms and Copper Contents · Comparative Radiosensitivity of (Prof J Schubert), 375
Animals Pathology of Domestic, (K V F Jubb and P C Kennedy) Vol 1, *review* by Dr A R Jennings, 722
Annealing by Compression following Chemical Radiation Damage in Potassium Bromate (T Andersen), 1094
Annelids (R Phillips Dales), *review* by N Tebble, 619
Annual of the British School at Athens, No 57, *review* by P Warren, 824

Anodic Oxide Films on Aluminium X-ray Emission Spectroscopic Investigation of Sealing of (Dr R C Spooner and W J Forsyth), 1002
Anomalous Behaviour of some Amino-Acids as Ice Nucleators (N Barthakur and Dr J Maybank), 866
Anomalous Electron Scattering in Dilute Silver-Manganese Alloys and its Analogy with the Ramsauer Effect (Dr M S R Chari), 875
Anomaly of Aldolase in Primary Liver Cancer (F Schapira, J-C Dreyfus and G Schapira), 995
Anopheles freeborni · Asynapsis of the Salivary Chromosomes of Hybrids between *Anopheles punctipennis* and (R H Baker and Prof J B Kitzmiller), 1023
Anopheles (*Cellia*) *gambiae* Giles Oviposition on Dry Surfaces by (L K H Goma), 1232
Anopheles minimus flavirostris Ludlow Transmission of Filariasis in the Philippine Islands by (Prof L E Rozeboom and Dr B D Cabrera), 915
Anopheles punctipennis and *Anopheles freeborni* Asynapsis of the Salivary Chromosomes of Hybrids between (R H Baker and Prof J B Kitzmiller), 1023
Anopheles quadrimaculatus Larvæ with the Surrounding Medium Rate of Equilibration of the Contents of the Gut of (Dr S Friedman), 605
Anophthalmia Frequencies of Teratologies among Homozygous Normal Mice compared with those Heterozygous for (Dr S L Beck), 810
Anorexia produced by Direct-current Blockade of the Vagus Nerve (J H Peñaloza-Rojas and Dr M Russek), 176
Antarctic Discovery II in the (John Coleman-Cooke), *review* by Dr L Harrison Matthews, 967
Antarctic Expedition The Royal Society International Geophysical, Vol 2, (general editor Sir David Brunt), *review* by Dr R Stoneley, 966
Ante-natal Determinant of Intelligence (J E Orme), 1239
Anthropology of Southern Nigeria The Physical (the late P A Talbot and H Mulhall), *review* by D R Brothwell, 981
Anti-anaphylactic Action of Acetylsalicylate in Guinea Pig Lung (H O J Collier, A R Hammond and B Whiteley), 176 , *erratum* 525
Antiarrhythmic Action Pharmacological Action of Ajmaline, the Possible Mechanism of its (Prof M L Chatterjee and M S De), 1067
Antibiotic on the *in vitro* life of Rumen Holotrich Protozoa Influence of Time of Addition of (D B Purser and H H Weiser), 290
Antibiotics *The Public Health Aspects of the Use of Antibiotics in Food and Feedstuffs* (World Health Organization), 1267
Antibiotics and of their Decomposition Products in the Presence of Cation Exchange Resins Hydrolysis of Some (Prof M G Brazhnikova and M K Kudinova), 167
Antibodies, *British Medical Bulletin*, 19, No 3 , September 1963, 1051
H-Antibodies in Anti-HeLa Sera H-Antigen in HeLa Cells and (G Brand et *al*), 362
Antibodies in Thymocytes (Gabrielle Horvath), 185
Antibody in Tissue Culture Formation of (L J Alfred et *al*), 698
Antibody Response Template Requirement in the Primary (Dr K M Stevens), 1017
Antibody Response initiated *in vitro* Transfer to Neonatal Chickens of the Primary (E F Gold and Prof A A. Benedict), 696
Anticoagulant, A New, Vitamin B_6 Results of a Comparative Study with Hydroxychloroquine Sulphate, *in vitro* (Prof E H Mandel), 590
Anticoagulant Action of Adenosine Triphosphate (Dr A J Quick), 469
Antidiuretic Hormone on Permeability of Single Muscle Fibres Effect of (Dr J A Zadunaisky et *al*), 365
Antidote, Vitamin B_6 as an, against the Rodenticide 'Castrix' (2-Chloro-4-methyl 6-dimethylaminopyrimidin) (O Karlog and E Knudsen), 790
Antifungal Activity of Some 2-Nitro-1-phenyl-1-phenylthioalkanes (Dr N G Clark, A F Hams and B E Leggetter) 171
Antigen Preparation of *Vipera palestinae* Antineurotoxin using Carboxymethyl-cellulose-bound Neurotoxin as (C Moroz et *al*), 697
H-Antigen in HeLa Cells and H-Antibodies in Anti-HeLa Sera (Prof G Brand, E Yunis and J J Yunis), 362
Antigen, The Cl^a (Caldwell) , a New and Rare Human Blood Group Antigen related to the *MNSs* System (Dr J Wallace and M M Izatt), 689
Antigens extracted from Green Tissues Serological Relationships with (W G Tucker), 597
Antihæmophilic Factor Gene Expression in Heterozygotes and Synthesis of Plasma (Dr L I Woolf), 481
Antihæmophilic, Stimulation of Factor VIII, Activity by Transfused Serum (Dr P. Fantl and R J Sawers), 1214
Antilymphocytic Serum on the Survival of Skin Homografts in Rats Effect of Lymphocyte Depletion by Thoracic Duct Fistula and Administration of (Prof M F A Woodruff and N A Anderson), 702
Antimony-124 Radioactive Decay of (A Seshagiri Rao et *al*), 750
Antimycin to Fish Toxicity of (P H Derse and Prof F M Strong), 600
Anti-œstrogenic Effects of Bovine Pineal Glands (Prof T Juszkiewicz and Dr Z Rakalska), 1329
Antirheumatic Drug, A New (S S Adams et *al*), 271
Antitetanic Serum Production Correlation between the Reaction of Horses to a Pyrogen and their Immunological Responses in (L Chiosa et *al*), 286
Antiviral Activity of Tenuazonic Acid (F A Miller et *al*), 1338
Ants Systematics of (W Leutert), 496
Aoki, H , et *al* Phytotoxic Metabolites of *Rhizoctonia solani*, 575
Aoki, N , et *al* Fundamental Function of Ac-globulin and Lipid in Blood Clotting, 1014
Apothecaries, A History of the Worshipful Society of, of London, Vol I 1617–1815, *review* by Prof K J Franklin, 721
Apparent Inability of Polypeptides constructed from D-Amino-acids to stimulate Antibody Formation (Dr G Zubay), 483
Appendix of the Rabbit A Homologue of the Bursa in the Chicken ? (O K Archer, D E R Sutherland and Prof R A Good), 337
Appetite in Sheep Chemostatic Regulation of (J M Holder), 1074
Apple, Branch, Stem and Collar Rot of, caused by *Phytophthora* Species of the '*cactorum* Group' (Dr G W F Sewell and J F Wilson), 1229
Apple Fruitlets A Comparison of Plant Cell Division Inducers from Coconut Milk and (J A Zwar et *al*), 679
Apple Fruits Non-climatic Factors affecting the Shape of (Prof M N Westwood and L T Blaney), 802
Apple Scald Induction by Anaerobiosis, 1229 (Dr D R Dilley, Dr R R Dedolph, D C MacLean and Prof D H Dewey), 1229
Application of Mathematical Statistics to Chemical Analysis (V V Nalimov), *review* by O F Newman, 987
Aquatic Plants Stomatal Distribution in Relation to Xeromorphy in (P K Mohanty and D Mishra), 909
Aqueous Solutions Photovoltaic Phenomena in (M Heyrovsky and Prof R G W Norrish), 880
Aqueous Suspensions of some Reactive Solids Rheology of Dilute (A K Chatterji and G W Kapse), 868
Arachin Variant Forms of (M P Tombs), 1321
Archer, Olga K , et *al* Appendix of the Rabbit A Homologue of the Bursa in the Chicken ?, 337
Argon Emission Lines radiated by the Low-voltage-High-amperage Arc compared with Four High-voltage Type Arcs Intensity of Neutral (C Mitchell), 1194
Arima, K , and Izaki, K Accumulation of Oxytetracycline Relevant to its Bactericidal Action in the Cells of *Escherichia coli*, 192
  Disappearance of Oxytetracycline Accumulation in the Cells of Multiple Drug-resistant *Escherichia coli*, 384
Armstrong, Prof D A , and Lee, R A Radiolysis of Gaseous Hydrogen Halides, 552
Arnold, Prof A H M An Introduction to Advanced Electrical Engineering, *review*, 819
  Electrical Instruments and Measurements, second edition, *review*, 987
  Examples in Advanced Electrical Engineering, *review*, 520
  Magnetic Amplifier Analysis, *review*, 394
Arnold, Dr W A Awarded the 1963 Kettering Award, 317
Aronowitz, L et *al* Effect of Capacitor Arrangement on the Symmetry of Linear Pinch Discharges, 59
Arousal Reactions with a Brief Partial- and Whole-body X-ray Exposure (E L. Hunt and Dr D J Kimeldorf), 536
Arroyo, E , et *al* Tumour-enhancing Activity of the Active Principles of *Croton tiglium* L , 1115
Arterial Hypertension and Ischaemic Heart Disease Comparison in Epidemiological Studies (World Health Organization Public Health Papers), 408
Arteriosclerosis Abnormal Glucose Tolerance in Repeatedly Bred Rats with (Prof B C Wexler and Dr C T Fischer), 133
  Hyperplasia of the Islets of Langerhans in Breeder Rats with (Prof B C Wexler and Dr C T Fischer), 33
Arthropod-borne Viral Infection Use of a Combined Complement-fixing Antigen to Detect (D E Carey), 1024
Aryl-Carboxylates of Copper II Magnetic Properties of some (Prof J Lewis and R C Thompson), 468
Ascaris lumbricoides Action of Piperazine on the Neuromuscular System of (Prof J del Castillo et *al*), 706
Ascorbic Acid 2,5-Dihydro-2-Furoic Acid A Product of the Anaerobic Decomposition of (I M Coggiola), 954
Ascorbic Acid of Liver Glycogen Depletion in Endotoxin Intoxication Prevention by (Prof T Fukuda and T Koyama), 1327
Ascospore and its Appendages in the Marine Fungus *Ceriosporopsis* Development of the (Dr I M Wilson), 601
Asfeld, L , and Schwartz, Prof D Structure of Carboxyl Groups in Humic Acids, 569
Asher, W C Effects of 2-Chloroethyltrimethylammonium Chloride and 2,4-Dichlorobenzyltributyl Phosphonium Chloride on Growth and Transpiration of Slash Pine, 912
Ashwood-Smith, Dr M J , and Leong, Dr G F Protective Effect of Deep-Body Hypothermia on X-ray-induced Mitotic Aberrations of Regenerating Rat Liver, 46
Assimilation Rate Method of Calculating Net (A J Vernon and J C S Allison), 814
Association of Scientific Workers *Science and Adult Education*, 834
Association of Teachers in Technical Institutions *Technical Teacher Training*, 939
Association of the British Chemical Manufacturers *British Chemicals and their Manufacturers*, 315
Association pour l'Etude Taxonomique de la Flore d'Afrique Tropicale, report by F N Hepper of the fifth plenary meeting, 530
Astrophysics Visiting Fellowships in, 737
Asundi, R K , and Dixit, R. M Fluorescence Spectrum of Di-cæsium Uranyl Nitrate, 668
Asymmetric Synthesis of α-Amino-acids by the Strecker Synthesis (Dr K Harada), 1201
Asynapsis of the Salivary Chromosomes of Hybrids between *Anopheles punctipennis* and *Anopheles freeborni* (R H Baker and Prof J B Kitzmiller), 1023
Atkinson, Dr M R , and the late Prof R K Morton Oxidative Phosphorylation and Related Processes, 221
Atlas de Thrombodynamographie (G Marchal, M E Leroux et M Samama), *review* by Dr A A Sharp, 981
Atmosphere at any Location A Rapid Method for Determining the Corrosivity of the (D P Doyle and H P Godard), 1167
Atmospheric Heating in the Auroral Zones (Dr L G Jacchia and J Slowey), 458
Atomic Oxygen-Graphite System Reaction Kinetics of the (C E Gleit et *al*), 69
Atomic Physics Today (Prof O R Frisch), *review* by S Weintroub, 203
Atomic Reactions Mechanism of Formation of Excited CN in (Dr D W Setser and Dr B A Thrush), 864
Attenuated Total Reflectance Spectra of Glycyl-L-alanine in Aqueous Solutions (Prof F S Parker), 1093
Auerbach, Dr Charlotte Mutation, Part I, *review* by Dr A Howard, 4
  The Science of Genetics, *review* by Dr A Howard, 4
Auroral Zones Atmospheric Heating in the (Dr L G Jacchia and J Slowey), 458
Austin, J W , et *al* Multiple Anomalies occurring in a New-born Spanish Goat following Prenatal Gamma-radiation, 906
Australian Journal of Chemistry as from 1964 a monthly publication, 315
Autointoxication in the Honey Bee 'Psychogenetic Stress' and (R J Pence et *al*), 930
Automata Theory to Problems in Information Retrieval The Application of (R A Kirsch), 1050
Automation Logic, Computing Machines, and (Alice Mary Hilton), *review* by Dr J J Florentin, 987
Autoradiographic Studies of *X*-chromosome Duplication in an *XO*/*X*-isochromosome X Mosaic Human Female (O J Miller, B B Mukherjee, S Bader and A C Christakos), 918
Autoradiographic Technique Studies of Radiation-induced Changes in Cellular Proliferation using a Double Labelling (Dr D R Davies and Dr D E Wimber), 229
Auxin-induced Cell Elongation Hydroxyproline as an Inhibitor of (Prof R Cleland), 908
Avian Coccidiosis (*Eimeria tenella*) Role of Cellular Factors in the Mediation of Immunity to (P L Long and Dr A E Pierce), 426
Avian Erythrocytes by Partial Electrocytolysis Isolation of Nuclei from (B R A. O'Brien), 1219
Awards, 1963, 1268
Axial Migration of Particles in Poiseuille Flow (A Karnis, H L Goldsmith and S G Mason), 159
Azo-dye Induced Hepatomas of Rats Loss of Liver Cell Antigens in (V I Kalnins and Prof H F Stich), 189
Azotobacter vinelandii prepared by Lysis with Phage A22 Nitrogen Fixation in Cell-free Extracts of (Dr M W Nimeck et *al*), 709

BACHMAN, Prof C H Geomagnetic Parameters and Psychiatric Hospital Admissions, 626
Bacillus megatherium · Independence of the Formation of Extracellular Protease on the Amino-acid Level in the Cells of (Dr J Chaloupka *et al*), 885

INDEX

Bacon, G E Neutron Diffraction, second edition, *review* by S Weintroub, 824
Bacteria Detergent (Sodium Lauryl Sulphate)- splitting Enzyme from (Prof Y C Hsu), 1091
  Effect of Kinetin on (Prof J C Maruzzella and J G Garner), 385
  Evaluation of Colorimettic Methods in the Estimation of Sialic Acid in (Dr G T Barry et *al*), 806
Bacteria from Solid Media Facilitation of the Removal of the Total Surface Growth of (P G D Naylor), 1232
Bacterial Blight of Cotton in Albar Resistance to (N L Innes), 387
Bacterial Growth Water-soluble Products of Methyl Cholanthrene and Their Effect on (Prof G T Johnson), 805
Bactericidin Hæmolytic Complement and Serum (Dr P H Kopper), 1332
Bacteriochlorophyll by *Rhodopseudomonas spheroides* under Dark aerobic Conditions Synthesis of (M Higuchi and G Kikuchi), 1191
Bacteriology Prof R G White appointed to the Gardiner chair of, 118
Bacteriology for Dairy Students (Dr A Seaman), *review* by D A McKenzie, 978

Chick Glycogenolysis in Aliquots of Glycogen Bodies of the (Dr A M Lervold and Dr J Szepsenwol), 81
Chick Cells Effect of Actinomycin D on Interferon Production by 'Active' and 'Inactive' Chikungunya Virus in (Dr G E Gifford and Dr E Heller), 50
Chick Embryo Fibroblasts to Nucleic Acids and Related Compounds Interferon Responses of (Dr K E Jensen et *al*), 433
Chicken ? A Homologue of the Bursa in the (O K Archer et *al*), 337
  Effect of Neonatal Thymectomy, Bursectomy and Thymo-bursectomy on Hæmagglutinin Production in (Dr K Isakovic et *al*), 273
  Experimental Allergic Thyroiditis in the (Prof B D Jankovic and Dr K Mitrovic), 186
  Influence of Acetylsalicyclic Acid on the Body-temperature of Heat-stressed (Prof B Glick), 603
  Selenium Content of Fresh Eggs from Normal and Dystrophic (H H Taussky et *al*), 1211
Chieffi, Prof G , and Botte, V Histochemical Reaction for Steroid 3β-ol-dehydrogenase in the Interrenal and the Corpuscles of Stannius of *Anguilla anguilla* and the *Conger conger*, 793
Chikungunya Virus in Chick Cells Effect of Actinomycin D on Interferon Production by 'Active' and 'Inactive' (Dr G E Gifford and Dr E Heller), 50
Chimerism between Two Closely Related Lines of Mice . Establishment and Stability of (Dr A J S Davies et *al*), 1222
Chinese Character Indexes (Ching-yi Dougherty, Sydney M Lamb and Samuel E Martin) Vols 1–5 *review* by Prof A D Booth, 392
Chiosa, L , et *al* Correlation between the Reaction of Horses to a Pyrogen and their Immunological Responses in Antitetanic Serum Production, 286
Chitinase from Gut of the Cockroach *Periplaneta americana* (R F Powning and H Irzykiewicz), 1128
Chlamydomonas Transmission and Segregation of a Non-chromosomal Factor controlling Streptomycin Resistance in Diploid (N W Gillham), 294
Chloramphenicol and Uptake of Salt in Plants (R J Ellis), 596
Chloramphenicol as a Basis for the Inhibition of Ion Accumulation Uncoupling Action of (Prof J B Hanson and T K Hodges), 1009
Chloramphenicol on the Uptake of Salts and Waters by Intact Castor Oil Plants. Effect of (Dr D J F Bowling), 284
2-Chloroethyltrimethylammonium Chloride and 2,4-Dichlorobenzyltributyl Phosphonium Chloride on Growth and Transpiration of Slash Pine Effects of (W C Asher), 912
2-Chloro-4-methyl-6-dimethylaminopyrimidin Vitamin B_6 as an Antidote against the Rodenticide 'Castrix' (O Karlog and E Knudsen), 790
Chloroplasts and the Synthesis of Proteins in Leaves Development of (Dr M J C Rhodes and Prof E W Yemm), 1077
Chlorpromazine Some Effects of, on the Activity of Pig Serum Cholinesterase (Prof W T Oliver, H S Funnell and Y Oki), 361
Cholesterol and Lipid Metabolism in the Rat Effect of β-Sitosterol on (T Gerson et *al*), 579
Choline Oxidase in Rat Liver and Kidney Histochemical Localization of (S Guha and R Wegmann), 1218
Cholinesterase Evidence for Non-allelism between Genes Affecting Human Serum (Prof H Harris et *al*), 1185
  Some Effects of Chlorpromazine on the Activity of Pig Serum (Prof W T Oliver et *al*), 361
Chrispeels, M J , and Vatter, A E Preservation of the Ultrastructure of Plant Cells using Glutaric Acid Dialdehyde as a Fixative, 711
Christakos, A C , et *al* Autoradiographic Studies of *X*-chromosome Duplication in an *XO*/*X*-isochromosome *X* Mosaic Human Female, 918
Christmas Lectures, 1268
Chromatographic Behaviour Effect of Ultra-violet Irradiation of Ribonucleic Acid on its (Dr H Kubinski), 595
Chromatographic Column Effect of the Compressibility of the Carrier Gas on the Experimentally Determined Number of Plates of a (Prof M J E Golay), 776
Chromatography Columns *in situ* Rejuvenation of Gas Liquid (D S Payn et *al*), 467
Chromatography in Investigation of Fruit Volatiles Fast-scan Mass Spectrometry with Capillary Gas-liquid (W H McFadden and R Teranishi), 329
Chromium 25 per cent Nickel Niobium Stabilized Austenitic Steel by Irradiation with Thermal Neutrons Elevated Temperature Embrittlement induced in a 20 per cent (A C Roberts and D R Harries), 772
X-Chromosome Duplication in an *XO*/*X*-isochromosome *X* Mosaic Human Female Autoradiographic Studies of (O J Miller et *al*), 918
Chromosome Number in a *Ribes* Hybrid following Treatment with *para*-Fluorophenylalanine Somatic Reduction of (Dr R L Knight, *et al*), 1341
Chromosomes Biometrics of the Karyotype of *Protemnodon bicolor*, with Reference to the Limitations in Accuracy of Identifying Human (R C Moore and Dr G Gregory), 234
  A Maternal Factor which Breaks Paternal (Prof M Levitan), 437
Chromosomes in Diploid and Polyploid Species of Wheat Temperature Sensitivity of (Dr H K Jain and R S Rana), 499
Chymotryptic Digest of Ovine Prolactin Preparation of a Low Molecular Weight Component with Lactogenic Activity from a Limited (Dr M Sluyser and Prof Choh Hao Li), 1007
Cinader, Prof B , and Dubiski, S An Alpha-globulin Allotype in the Mouse (*MuBl*), 781
Circular Dichroic Studies of Synthetic Polypeptides (Dr J Brahms and Dr G Spach), 72
Citrate as an Intermediary in the Inhibition of Phosphofructokinase in Rat Heart Muscle by Fatty Acids, Ketone Bodies, Pyruvate, Diabetes and Starvation (P B Garland, Dr P J Randle and E A Newsholme), 169
Citrus Yellow Vein Virus Use of Synergy in the Identification of Strains of (Dr L G Weathers), 812
Civil Research Policy (Prof R J Sarjant), 24
Civil Science Committee of Enquiry into the Organization of (Cmnd 2171), 928, 1029, 1245
Civil Science in Britain Administration of Education and, 1245

    Plasma Physics and Magnetofluidmechanics, *review*, 962
    Plasma Physics and Thermonuclear Research, Vol 2, *review*, 962
    Proceedings of the Symposium on Electromagnetics and Fluid Dynamics of Gaseous Plasma, New York, 1961, *review*, 962
Cooper, Prof N S , et *al* Role of Complement in Nephrotoxic Nephritis, 373
Cooper, P J Quantitative Organic Analysis via Functional Groups, third edition, *review*, 969
Copley Medal awarded to Sir Paul Fildes, 631, 1255
Copolymers Fluorescence of Styrene Homopolymers and (Dr S S Yanari et *al*), 242
Copper Ultrasonic Excitation of Nuclear Magnetic Resonance of the Copper-63 and Copper-65 Nuclei in a Single Crystal of (D J Barnes), 253
Copper II Magnetic Properties of some Aryl-Carboxylates of (Prof J. Lewis and R C Thompson), 468
Copper by Wood Constituents Sorption of (D E Bland), 267
Copper Contents Comparative Radiosensitivity of Animal Organisms and (Prof J Schubert), 375
Copper Ions Blocking the Ninhydrin-Schiff Reaction with (Dr Gy Rappay), 274
Copper Ions in Radiobiological Damage Possible Role of (Prof M Anbar), 376
Copping, Prof A M Progress in Nutrition and Allied Sciences, *review*, 201
Corkum, P B , and Magarvey, R H The Wake of a Rising Bubble, 354
Cornelius, Prof C E Relation of Body-weight to Hepatic Glutamic Pyruvic Transaminase Activity, 580
Corner, E J H Symposium on the Impact of Man on Humid Tropics Vegetation, Goroka, Territory of Papua and New Guinea, 1960, *review*, 991
Cornman, Dr I Toxic Properties of the Saliva of *Cassis*, 88
Corpuscles of Stannius of *Anguilla anguilla* and *Conger conger* Histochemical Reaction for Steroid-3β-ol-dehydrogenase in the Interrenal and the (Prof G Chieffi and V Botte), 793
Correlation between Rheumatic Diseases and Rh Blood Groups (Dr A S Cohen, Prof W C Boyd, Dr S Goldwasser, Dr E S Cathcart and Dr M Heisler), 1215
Correlation between the Reaction of Horses to a Pyrogen and their Immunological Responses in Antitetanic Serum Production (L Chiosa, Dr N Muntiu, C Constantinescu, Gh Prelipceanu and I Boncicat), 286
Cortical Blood Flow Relationship between Venous Pressure and (I Jacobson *et al*), 173
Corvazier, P , et *al* Formation of Antibody in Tissue Culture Effect of Certain Mucopolysaccharides and Hexosamine, 698
Cosgrove, D J , and Tate, M E Occurrence of *neo*-Inositol Hexaphosphate in Soil, 568
Cosmic Radiation Sodium-24 produced by (W Rodel), 999
Cosmic Radiation, A Solar Anisotropy in, viewed from a Terrestrial Frame of Reference (R M Jacklyn), 1306
"Cosmic Rays", Eighth International Conference on, 218
Cosslett, Dr V E Tabellen zur angewandten Physik, Band I, *review*, 303
Cotterell, Dr B Cleavage Fracture of Polycrystalline Aggregates, 161
Cotton Inoculum Potential and the Fusarial Wilt of (Dr A S Rao and M V Rao), 598
Cotton Cellulose Gas Yields from Electron-irradiated (Dr F L Dalton et *al*), 862
Cotton in Albar Resistance to Bacterial Blight of (N L Innes), 387
Cotton Leaf Worm, *Prodenia litura* (F) induced by Radioactive Males Inhibitory Effect of L-Methionine-methyl-^{14}C on Oviposition by Females of the (Prof A A Abdel-Malek), 604
Coumarin Fungistatic Action of (Dr J S Knypl), 800
Council of Scientific and Industrial Research, New Delhi Publications, 735
Courts, A Collagen Research in Czechoslovakia, 322
Couch, Prof H B Diseases of Turfgrasses *review* by Dr E Griffiths, 104
Crab Nebula by the Solar Corona in June 1963 Occultation of the (J D Wyndham and B G Clark), 766
Crabbe, Dr J Site of Action of Aldosterone on the Bladder of the Toad, 787
Craig, G Y Preparation and Publication of Geological Journals, 739
    Principles of Paleoecology, *review*, 1035
Crandell, Major R A , and Hillis, Capt W D Effect of Ether on Rabies Virus, 715
Cranial Exposure to X-rays Changes in the Esterases of Rat Brain and Blood Serum following Acute (Dr E B Masurovsky and Dr C R Noback), 847

Cranial Nerve in *Lacerta vivipara* Posterior Division of the Eighth (Dr **D. W.** Hamilton), 705
Craplet, C The Dairy Cow, *review* by Dr J A B Smith, 5
Craver, B N , *et al* New Chemical Structure with Specific Depressant Effects on the Amygdala and on the Hyper-irritability of the 'Septal Rat', 369
Crawford, Dr J M , et *al* Excitation of Cerebellar Neurones by Acetylcholine, 579
  Strychnine-Resistant Central Inhibition, 843
Cremona, Dr T , et *al* Conversion of DPNH Dehydrogenase to DPNH-cytochrome Reductase by Thiourea, 673
  Labile Flavin Adenine Dinucleotide of Heart Muscle Preparations, 958
Cremona, Dr T , and Kearney, Dr E B Resolution of some Problems concerning the Reduced Diphosphopyridine Nucleotide Dehydrogenase of the Respiratory Chain, 542
Crenuchus Frontal Foramina and Tripodes of the Characin (Dr R McN Alexander), 1225
Critchley, J K , and Lott, R J Equilibrium Diagram for the Nickel-Cadmium System 773
Crook, M A Solvent Retention and Gel Formation in Polyvinyl Chloride, 132
Cross, Dr M J , et *al* Inhibition of the Aggregation of Blood Platelets by Nucleosides, 138
Cross-relations of *Escherichia* and Human Red Cells (Miss B J Ten Raa and Dr C R Macpherson), 182
Croton tiglium L Tumour-enhancing Activity of the Active Principles of (Prof B L Van Duuren *et al*), 115
Crounse, Dr R G Epidermal Keratin A Re-evaluation, 539
Crowther, A F Pharmaceutical Chemistry Plenary Lectures presented at the International Symposium on Pharmaceutical Chemistry, Florence 1962, *review*, 978
Crustacea Homarine (*N*-Methyl Picolinic Acid) in Muscles of some Australian (G J Leonard and K Macdonald), 78
Crystal Growth during the Hydration of $CaSO_4 \frac{1}{2}H_2O$, (Dr S Chatterji and Dr J W Jeffery), 463
Crystalline State Hydrogen-bond Energies in the (Dr M Davies and B Kybett), 776
Crystallographic Data of Two Seleno-urea Derivatives (M P Rodriguez, Dr M Cubero and A L Castro), 1091
Crystallography International summer school in "Experimental X-ray Crystallography" to be held in 1964, 941
Crystals X-ray Asterism and Work-hardening in (Prof J G Byrne), 254
  X-ray Intensity Statistics of a Pair of Related (G N Ramachandran and R Srinivasan), 1090
Crystals of the Tobacco Mosaic Virus Protein Formation of True Three-Dimensional (R MacLeod *et al*), 932
Csapo, Dr A I , and Takeda, Dr H Electrical Activity of the Parturient Human Uterus, 680
Cubero, Dr M , et *al* Crystallographic Data of Two Seleno-urea Derivatives, 1091
Culex pipiens after X-irradiation A Red Eye Colour Mutation in (A Wild), 917
Cullen, J R , et *al* Deterrent Effect of Insecticides on Malaria Vectors, 860
Culling, C F A , *et al* Electrical Charge Density of Spleen Cells sensitized against *L*-strain Fibroblasts, 691
Cullum Geographical Medal awarded to Miss Rachel Carson, 1052
Cultivation of Horsesickness Virus in Tissue Culture (B J Erasmus), 716
Cumings, Prof J N International Review of Neurobiology, Vol 4, *review*, 395
Cumming, R A , et *al* Fibrinolytic System in Certain Congenital and Hereditary Hæmorrhagic Disorders a Critical Evaluation of the Theory of Dynamic Hæmostasis, 478
Cummings, A J , and Martin, Dr B K Excretion and the Accrual of Drug Metabolites, 1296
Cundall, J A , and Newman, P C Superlattice Structure in Ga_2Te_3, 876
Cunningham, Prof G J Histochemistry Theory, Practice and Bibliography, *review*, 619
Cunningham, R K , and Nielsen, K F Evidence against Relationships between Root Cation Exchange Capacity and Cation Uptake by Plants, 1344
Cunningham, Dr W L appointed to a research fellowship in Biological Chemistry, 837
Curl, jun , Dr H , et *al* Acceleration of Sinking Rates of Radionuclides in the Ocean, 1276
Current-Voltage Relations for Mobility-controlled Sheaths , a Simple Method for Determining Ion Mobility (Dr M A Weinstein and Dr C Kenty), 873
Curtis, A S G Effect of *ph* and Temperature on Cell Re-aggregation, 1235
Curtis, Dr D R , et *al* Excitation of Cerebellar Neurones by Acetylcholine, 579
  Strychnine-Resistant Central Inhibition, 843
Curzon, A E , et *al* Use of an Electron Beam for detecting Superconducting Domains of Lead in its Intermediate State, 157
Cushing, Dr D Plankton and Productivity in the Oceans, *review*, 975
Cuthbert, Dr M F , et *al* Quaternized Sympathomimetic Amines, 270
Cuthberton, D P (edited by) Progress in Nutrition and Allied Sciences, *review* by Prof A M Copping, 201
Cuthbertson, Dr D P The Rowett Research Institute for Animal Nutrition Golden Jubilee, 635
Cyanide Intoxication Neuropathological Changes in Chronic (A D M Smith et *al*), 179
Cyanobromination of Lanthionine Formation of 2-Iminothiazolidine-4-carboxylic Acid in the (N J J van Rensburg), 672
Cyanole and Neutral Red in the Gaint Axon of the Squid Distribution of (Dr N N Nikolsky and Dr S A Krolenko), 280
Cyclitos, Les (Prof Theodore Posternak), *review* by Dr D M Brown, 989
Cycloheximide Inhibition of Protein Synthesis *in vitro* by (Dr M R Siegel and Dr H D Sisler), 675
*Cyclo*phosphamide Prolongation of Homograft Survival in Mice with Single Doses of (Dr M C Berenbaum and I N Brown), 84
Cygnus *Y* Radio Frequency Radiation from (Dr H C Ko), 1193
Cystathionase in Rat Liver Effect of DL-Ethionine on the Level of (F Chatagner and O Trautman), 75
Cysteamine and Cellular Sulphydryl Levels Radiation Protection by (Dr L Revesz and Helena Bergstrand), 594
Cysteic Acid-1-^{14}C bv Human, Dog, and Rat Liver and Brain Comparison of Decarboxylation of Cysteine Sulphinic Acid-1-^{14}C and (J G Jacobsen and Dr L H Smith, jun), 575
Cysteine Sulphinic Acid-1-^{14}C and Cysteic Acid-1-^{14}C by Human, Dog, and Rat Liver and Brain Comparison of Decarboxylation of (J G Jacobsen and Dr L H Smith, jun), 575
Cystine, Glutathione and Sulphur-containing Proteins Alkaline Degradation of (Dr F M Robbins and Dr J A Fioriti), 577
Cytochemical Method for Electron Microscopy (R Roppel and C Melton), 915
Cytochemistry Acid-buffered Acetone as a Fixative for Enzyme (Dr L S Kaplow and Dr M S Burstone), 690
Cytochemistry and Electron Miscroscopy by a Non-freezing Technique Preparation of Thick Sections for (Dr R E Smith and Dr M G Farquhar), 691
Cytochrome *c* A Histochemical Technique for the Demonstration of (Dr T Flatmark), 1112
Cytochrome *c* Biosynthesis Gaseous-ion-induced Stimulation of (Prof A P Krueger, et *al*), 707
Cytoplasmic Dimorphism within Pollen Grains (Prof D A Larson), 911
Cytoplasmic Ribonucleic Acid Site of Synthesis of (Prof H Harris and L F LaCour), 227

DACHILLE, Prof Frank Changes in the Earth's Axis due to large Meteorite Collisions, 415
Dahlia infected with Dahlia Mosaic Virus Inclusion Bodies in (S M Robb), 1339
Dairy Cow (C Craplet), *review* by Dr J A B Smith, 5
Dairy Students Bacteriology for (Dr A Seaman), *review* by D A McKenzie, 978
Dales, R Phillips Annelids, *review* by N Tebble, 619
Dallinga, G , et *al* Kinetics of Isotope Redistribution Reactions, 1316
Dalos, Dr B Limiting Factor in the Assay of Aldolase, 1013
Dalton, Dr F L , et *al* Gas Yields from Electron-irradiated Cotton Cellulose, 862
Dalton, John The Bicentenary of the birth of, 22
Daly, The Charles P , medal awarded to Prof H Darby, 1052
Damage to Livestock from Radioactive Fall-out (Dr C E Purdom), 946
D'Amico, R P , et *al* Lactic Dehydrogenase in *L*1210 Cells, 903
Danckwerts, Prof P V Science Versus Technology The Battle for Brains, 219
Dang-Vu-Bien, Mme , et *al* Constancy of Extrapolated Amount of Non-solvent Water in Cellulose, immersed in Different Salt Solutions of Varying Concentration, 358
Dangerfield, W G , and Faulkner, G Preservation of Starch-gel Electrophoresis Strips, 388
Daniel, M J Early Fertility of Red Deer Hinds in New Zealand, 380
Darby, Prof H Clifford Awarded the Charles P Daly Medal, 1052
Darlington, Prof C D Funktionelle und Morphologische Organisation der Zelle Wissenchaftliche Konferenz der Gesellschaft Deutscher Naturforscher und Arzte in Rottach-Egern 1962, *review*, 974
Darlington, Prof C D , and Bradshaw, A D (edited by) Teaching Genetics in School and University, *review* by Prof P M Sheppard, 976
Darveniza, Dr M Light Emission from Organic Liquids and Solids due to Excitation by High d c Fields, 558
Darwin, Dr Erasmus, and the Theory of Evolution (D G King-Hele), 304
Daszkiewicz, O K , et *al* Proton Magnetic Relaxation and Protein Hydration, 1006
Dating of Polarity Zones in the Hawaiian Islands (Dr I McDougall and D H Tarling), 54
Dating of Tropical Coastal Regression (Prof A S Boughey), 600
Dauvillier, Prof A Physique Solaire et Géophysique, *review* by J A Ratcliffe, 1
Davidson, Prof C F The Tectonics of the Canadian Shield, *review*, 303
Davies, Dr A J S , et *al* Establishment and Stability of Chimerism between Two Closely Related Lines of Mice, 1222
Davies, Dr C N Measuring Airborne Dust and Mist, 1269
Davies, Dr D A L , and Sanderson, Dr A R Enzymatic Activity of Mouse Histocompatibility Antigen Preparations, 32
Davies, D R , et *al* Heart Rate during Auditory Vigilance Performance, 1026
  Relative Biological Efficiency of Negative μ-Mesons and Cobalt-60 γ-Rays, 277
Davies, Dr D R , and Bateman, J L High Relative Biological Efficiency of 650-keV Neutrons and 250-kVp X-rays in Somatic Mutation Induction, 485
Davies, Dr D R , and Wimber, Dr D E Studies of Radiation-induced Changes in Cellular Proliferation, using a Double Labelling Autoradiographic Technique, 229
Davies, Dr J B Appointed lecturer in Electrical Engineering, 409
Davies, Prof J T , and Rideal, Prof E K Interfacial Phenomena, second edition, *review* by N K Adam, 1140
Davies, L W Heat Liberation in Alloy-junction Silicon Diodes, 1196
Davies, Dr M , and Kybett, Brian Hydrogen-bond Energies in the Crystalline State, 776
Davies, Prof R O Solid State Physics, Vols 12, 13 and 14, *review*, 722
  Theory of Lattic Dynamics in the Harmonic Approximation (Solid State Physics Supplement 3), *review*, 722
Davies, S Howard, et *al* Fibrinolytic System in Certain Congenital and Hereditary Hæmorrhagic Disorders a Critical Evaluation of the Theory of Dynamic Hæmostasis, 478
Davis, Mary, et *al* Disturbance in the Proliferation and Differentiation of Mononuclear Leucocytes to Fibroblasts in Diffusion Chambers by Deuterium Oxide, 591
Davis, R , et *al* Canine Endotoxin Shock Protection against a Lethal Dose of Endotoxin following an Infusion of Histamine, 475
Davy Medal awarded to Dr E J Bowen, 631, 1255
Dawes, Dr Ben (edited by) Advances in Parasitology, Vol 1, *review* by Dr G Lapage, 103
Dawes, Prof Ben Death of *Fasciola hepatica* L weaked by X-irradiation, 602
Day, D E Determining the Co-ordination Number of Aluminium Ions by X-ray Emission Spectroscopy, 649
D'Aeth, Prof R Proposal for an Educational Research Council and some of its Implications, 116
De, M S , and Chatterjee Prof M L Pharmacological Action of Ajmaline, the Possible Mechanism of its Antiarrhythmic Action, and its Therapeutic Possibilities, 1067

De Vos, B Appointed director of the Statistical Research Unit in Sociology, 1050
de Vries, Prof A , et *al* Action of Bovine and Human Pancreatic Phospholipase *A* on Lipoprotein-bound Phospholipids, 1096
  Preparation of *Vipera palestinae* Antineurotoxin using Carboxymethylcellulose bound Neurotoxin as Antigen, 697
DeWitt, C , et *al* (edited by) Geophysics The Earth's Environment—Lectures delivered at Les Houches, 1962, *review* by J A Ratcliffe, 1
de Zulueta, Dr J , et *al* Deterrent Effect of Insecticides on Malaria Vectors, 860
del Castillo, Prof J , et *al* Action of Piperazine on the Neuromuscular System of *Ascaris lumbricoides*, 706
de la Mare, Prof P B D *Obituary* of Prof E D Hughes, 20
Dean, Dr F M Naturally Occurring Oxygen Ring Compounds, *review* by Dr R Livingstone, 509
Death of *Fasciola hepatica* L weakened by X-irradiation (Prof Ben Dawes), 602
Deeley, Dr E M Progress in Control Engineering, Vol 1, *review*, 964
  Servomechanisms, *review*, 964

Deer, Prof W A, *et al* Rock-forming Minerals, Vols 2–5, *review* by Dr F C Phillips, 3
Deer Hinds, Red, in New Zealand Early Fertility of (M J Daniel), 380
Defandorf, Dr F M *Obituary*, 215
Defence (Transfer of Functions) Bill, 1264
Deficiency of Metals in Population II Stars (Prof G Wallerstein and Dr E M Burbidge, Prof S Bashkin), 1081
Degradation by Gamma-irradiation of Thymus Deoxyribonucleohistone in Solution (P H Lloyd and Dr A R Peacocke), 428
Degradation Products from Elastin (J Thomas, D F Elsden, S M Partridge), 651, (G R Bedford and A R Katritzky), 652
Dehydrogenase Activity during Transneuronal Atrophy Changes of (Prof C Kupfer), 80
Delayed Fluorescence of 3 4-Benzpyrene Solutions (Dr C A Parker), 331
Delphin, F Histology and Possible Functions of Neurosecretory Cells in the Ventral Ganglia of *Schistocerca gregaria* Forsk, 913
Delwaide, Dr P J, and Desmedt, Prof J E Neural Inhibition in a Bird Effect of Strychnine and Picrotoxin, 583
Denaro, Dr A R, et *al* Experiments in Physical Chemistry, *review* by D C Firth, 724
Dennis, Dr R W G Collins Guide to Mushrooms and Toadstools, *review*, 822
Density Homogeneity and Estimated Molecular Weight of Interferon (L E Kreuz and Prof A H Levy), 883
Deoxyribonuclease in Synthesis of Deoxyribonucleic Acid Role of (Prof N K Sarkar et *al*), 1205
Deoxyribonuclease Production by Staphylococci Significance of (S I Jacobs et *al*), 709
Deoxyribonucleic Acid Compounds Interfering in the Diphenylamine Test for (Dr J B Lee), 264
  Participation of Purine and Pyrimidine Nucleotide Sequences in the Molecule of Calf Thymus (V Habermann), 782
  Role of Deoxyribonuclease in Synthesis of (Prof N K Sarkar *et al*), 1205
  Thymidine-like Electron Spin Resonance Spectra in Gamma-irradiated (A Ehrenberg et *al*), 376
  X-irradiation of (Dr Shan-ching Sung and Prof J H Quastel), 781
Deoxyribonucleic Acid and the Ancestry of Wheat (M D Upadhya and Dr M S Swaminathan), 713
Deoxyribonucleic Acid by Transport Methods Concentration Effects in Measurements of Characteristics of (P K Ganguli), 164
Deoxyribonucleic Acid from Cells other than Leucocytes Re-utilization of (Prof K E Fichtelius and O Groth), 587
Deoxyribonucleic Acid Solutions in the 'Sub-melting' Temperature Range Viscosity of (A-M Freund and Dr G Bernardi), 1318
Deoxyribonucleic Acids of Marine Mollusca (M Smith and D B Quayle), 676
DNA Content Natural Occurring Variations in Rat Liver (Dr G Horvath), 261
DNA Injected into Total-Body Irradiated (600 R) Infantile Rats and Mice Recovery Effects of Homologous Testes (Miss N Savković), 1073
Deoxyribonucleohistone in Solution Degradation by Gamma-irradiation of Thymus (P H Lloyd and Dr A R Peacocke), 428
Department of Scientific and Industrial Research and Mullard Research Laboratories British Computer Development Project, 119
Dependency in Psychotherapy (Prof William U Snyder), *review* by Prof H J, Eysenck, 1135
Dermal Connective Tissue of Normal and Hypophysectomized Rats Acid Mucopolysaccharide Content of (Go Matsumura et *al*), 784
Dermatophytes Production of 6-Aminopenicillanic Acid by (Dr J Uri *et al*), 896
Derrien, Y *et al* Immunological and Starch-gel Electrophoresis Studies of the Carbonic Anhydrases X_1, X_2 and Y isolated from Human Erythrocyte Hæmolysates, 371
Derse, P H, and Strong, Prof F M Toxicity of Antimycin to Fish, 600
Desmedt, Prof J E, and Delwaide, Dr P J Neural Inhibition in a Bird Effect of Strychnine and Picrotoxin, 583
Desmedt, Prof J E, and LaGrutta, Dr V Function of the Uncrossed Efferent Olivocochlear Fibres in the Cat, 472
Detecting Fingerprints on Paper (Dr R L Grant, Dr F Lyth Hudson and Dr J A Hockey), 1348
Detection of Nitric Oxide by Gas-chromatography (P J Kipping and Dr P G Jeffery), 1314
Detection of Phosphorothioate Pesticides (D P Braithwaite), 1011
Detergent (Sodium Lauryl Sulphate)-splitting Enzyme from Bacteria (Prof Y C Hsu), 1091
Detergents Booklet describing the research activities of Procter and Gamble Ltd, 524
Determinants of Short-term Recall Number of Items presented and recalled as (L K Selzer and Prof W A Wickelgren), 1239
Determination of Cerebral Blood Flow by a Krypton-85 Desaturation Method (L C McHenry, jun), 1297
Determination of Radiation-induced Mutation Rates of Recessive Lethal Alleles in *Saccharomyces* (Dr W Laskowski and K Haefner), 795
Determination of the Non-zonal Harmonics of the Geopotential from Satellite Doppler Data (Dr W H Guier), 124
Determining the Co-ordination Number of Aluminium Ions by X-ray Emission Spectroscopy (D E Day), 649
Deterrent Effect of Insecticides on Malaria Vectors (Dr J de Zulueta and J R Cullen), 860, (A Smith), 860
Dethier, Prof V G The Physiology of Insect Senses, *review* by Prof V B Wigglesworth, 974
Deuterauxin, an Active Oxidation Product of Indolyl-3-Acetic Acid, and its Possible Role in the Mechanism of Plant Cell Wall Elongation (Dr A A Bitancourt), 548
Deuterium Oxide Disturbance in the Proliferation and Differentiation of Mononuclear Leucocytes to Fibroblasts in Diffusion Chambers by (Dr N L Petrakis et *al*), 591
Development of Bradycardia during Submersion of the Duck (O B Reite, J Krog and K Johansen), 684
Development of Chloroplasts and the Synthesis of Proteins in Leaves (Dr M J C Rhodes and Prof E W Yemm), 1077
Development of Modern Science (Sir Howard Florey), Substance of the first David Rivett Memorial Lecture delivered at the University of Melbourne, September 1963, 397, 405
Development of the Ascospore and its Appendages in the Marine Fungus *Ceriosporopsis* (Dr I M Wilson), 601
Devi, A, et *al* Role of Deoxyribonuclease in Synthesis of Deoxyribonucleic Acid, 1205
Dewey, Prof D H, et *al* Apple Scald Induction by Anaerobiosis, 1229
Dewey, Dr D L, and Hawes, Christine 6-Aminonicotinamide and the Radiosensitivity of Human Liver Cells in Culture, 1176

2-Iminothiazolidine-4-carboxylic Acid in the Cyanobromination of Lanthionine Formation of (N J J van Rensburg), 672
Immobilization of Elephant Seals using Succinylcholine Chloride (J K Ling and D G Nicholls), 1021
Immunochemical Analysis of Rabbit Gamma-globulin Allotypes (Dr A Feinstein, Prof P G H Gell and Dr A S Kelus), 653
Immuno-fluorescence Visualization of Poliovirus Type III in Paraffin Sections of Monkey Spinal Cord by Indirect (E Kovacs et *al*), 497
Immunological and Starch-gel Electrophoresis Studies of the Carbonic Anhydrases X_1, X_2 and Y isolated from Human Erythrocyte Hæmolysates (Dr J M Fine, G A Boffa, M Charrel, G Laurent and Y Derrien), 371
Immunological Changes and Therapeutic Effects of Convalescent Serum after Injury by Burns (L Koslowski, Dr B Urbaschek and R Versteyl), 273
Immunological Characterization of Vilyuisk Human Encephalomyelitis Virus (Dr J Casals), 339
Immunological Identification of a Rivanol 'Purified' Fraction of Macrocryoglobulinæmia (Waldenstrom) Serum (D Amsterdam and Dr L A Cohen), 341
Immunological Tolerance between Litter-mates in Sheep (Dr J Slee), 654
Immunologically Competent Cells and of Myeloid Cells Comparison of the Sensitivity to Storage at 37°C in Tyrode Solution of (J L Amiel and Dr G Mathé), 1224
"Impact of the Users' Needs on the Design of Data Processing Systems", joint conference on, 1155
Imperial College of Science and Technology, Commemoration Day, 632
  Nuffield Foundation Grant, 1050
  Substance of Prof Rupert Hall's Inaugural Lecture, 1141
Imperial College of Science and Technology and the Indian Institute of Technology (Delhi), 735
Impurities in Commercially Prepared Tritiated Folid Acid (Dr S P Rothenberg and Dr R Garcia), 922
Incidence of Squamous Cell Carcinoma in Mice Fed 9,10-Dimethylbenz(a)antracene (Dr A S Mulay), 1114
Inclusion Bodies in *Dahlia* infected with Dahlia Mosaic Virus (S M Robb), 1339
Increase in Radiocarbon from the most recent Series of Thermonuclear Tests (R Nydal), 212
Increased Concentrations of Blood Lipids in Guinea Pigs poisoned by Sarin (G S Fukuyama, P A Adie and E Ruth Hughes), 897
Independence of the Formation of Extracellular Protease on the Amino-acid Level in the Cells of *Bacillus megatherium* (Dr J Chaloupka, P Křečkova and L Ríhova), 885
Indian Botanical Society Awards, 1052
Indian Institute of Technology (Delhi) and the Imperial College of Science and Technology, 735
Indian Science Congress Association Reprint of presidential address, 1963, 939
Individual and Sub-group Antigenic Specificity of Bence-Jones Protein (Dr S Stein, Dr R L Nachman and Dr R L Engle, jun), 1180
Indole Derivatives Solvent Systems for Silica-gel Column Chromatography of (L E Powell), 79
Indolyl-3-Acetic Acid, and its Possible Role in the Mechanism of Plant Cell Wall Elongation Deuterauxin, an Active Oxidation Product of (Dr A A Bitancourt), 548
Indolyl-3-Acetic Acid as Influenced by Naturally Occurring Phenolic Acids *In vivo* Destruction of Exogenously applied (Dr M H Zenk and G Muller), 761
Indolyl Acids in Phenylketonuric Monkeys Excretion of (D E Boggs et *al*), 76
Induced Temperature Tolerance of Plant Tissue *in vitro* (Prof C A Schroeder), 1301
Induction by 5-Fluorouracil of Bacteriophage Development in Lysogenic *E coli* K12 (λ) (Dr H Marcovich and Prof H S Kaplan), 487
Induction of Fibrosarcoma in the Primate *Tamarinus nigricollis* (Prof B M Levy), 182
Induction of Viscous Metamorphosis in Human Blood Platelets by means other than by Thrombin (M Bettex-Galland, E F Luscher, G Simon and P Vassalli), 1109
Industrial and Agricultural Research in Belgium, 24
Industrial Participation Theory and Practice—a Case Study (J A Banks), *review* by T H Hawkins, 986
Industry Employment of Women in, 842
Infection Variation of Interferon Yield with Multiplicity of (Dr G E Gifford), 91
Infectious Bovine Rhinotracheitis Virus in Monkey Kidney Tissue Culture Cells Propagation of (Prof H Rouhandeh), 386
Infectious Diseases of the Honey-Bee (Dr Leslie Bailey), *review* by Dr M Delia Allen, 990

Infectious Phenol Extract of Tomato Spotted Wilt Virus-infected Tissue (Dr R J Best), 609
Influence of Acetylsalicyclic Acid on the Body-temperature of Heat-stressed Chickens (Prof B Glick), 603
Influence of Adrenocorticotrophic Hormone, Hydrocortisone and Hypophysectomy on the Distribution of β-Glucuronidase in the Adrenal Cortex of the Rat (Dr G Th A M Bots, Dr R G J Willighagen and Dr A Schaberg), 1111
Influence of Duration of Experiment on Rate of Uptake of Radioactive Potassium in Smooth Muscle (H Bauer, Dr P J Goodford and J Huter), 1104
Influence of Hydrostatic Pressure on Orientation in Electrophilic Aromatic Substitutions (D W Coillett and Dr S D Hamann), 166
Influence of Lactation on the Retention of a Single Dose of Strontium-90 in Rats (Dr W E Kollmer and Dr H Kriegel), 187
Influence of Radio Frequency Heating on Sperm (Dr D Makow and Dr H Grice), 1120
Influence of Time of Addition of Antibiotic on the *in vitro* Life of Rumen Holotrich Protozoa (D B Purser and H H Weiser), 290
Influence of Trypan Blue on Resorption of Rat Embryos (W N Adams Smith), 699
Influence on Capillary Permeability of Lymph discharged from a Scald (Dr I A Oyvin, S M Shegel and E G Yagodkina), 270
Infra-red Spectra of Embryonic Chick Feathers (Dr R A Malt and K A Hartman, jun), 703
Infra-red Spectrum of Nitrogen Dioxide (NO_2) Magnetic Effects in the Far (Dr H A Gebbie et *al*), 1304
Inhibition by Urethan (Ethyl Carbamate) of Virus Induction of Leukæmia on *C3H* Mice (Dr L W Law and A Precerutti), 692
Inhibition of Protein Synthesis *in vitro* by Cycloheximide (Dr M R Siegel and Dr H D Sisler), 675
Inhibition of Pyridine Nucleotide Transhydrogenase by Dicumarol (Prof J McGuire, LeRoy Pesch and Helen Fanning), 71
Inhibition of Pyruvate Metabolism in Mitochondrial Suspensions by Cobalt (J T Dingle and M Webb), 1208
Inhibition of the Aggregation of Blood Platelets by Nucleosides (Sonia Clayton, Prof G V R Born and Dr M J Cross), 138
Inhibition of the Photoreduction of Flavin Mononucleotide (Dr G K Radda and Prof M Calvin), 464
Inhibition of the Smooth Muscle of the Taenia Coli (Dr G Burnstock, G Campbell, M Bennett and Dr M E Holman), 581
Inhibitory Aspects of Bile Secretion (Dr T Hargreaves and Prof G H Lathe), 1172
Inhibitory Effect of L-Methionine-methyl-^{14}C on Oviposition by Females of the Cotton Leaf Worm, *Prodenia litura* (F) induced by Radioactive Males (Prof A A Abdel-Malek), 604
Inhibitory Effects of Œstrogens on Augmented Activity of Endometrial Carbonic Anhydrase caused by 4,4'-Methylenedianiline (Dr K Yamashita), 81
Initial Effects of Ionizing Radiations on Cells A Symposium held in Moscow, 1960 (edited by R J C Harris), *review* by Dr P J Lindop 1036
Innes, N L Resistance to Bacterial Blight of Cotton in Albar, 387
Inoculum Potential and the Fusarial Wilt of Cotton (Dr A S Rao and M V Rao), 598
Inorganic Adduct Molecules of Oxo-Compounds (Ingvar Lindqvist), *review* by Dr G W A Fowles, 969
Inorganic Chemistry Dr R Mason appointed to the chair of, 409, 632
  Prof B O West appointed to the chair of, 734
neo-Inositol Hexaphosphate in Soil Occurrence of (D J Cosgrove and M E Tate), 568
Insect Anatomy A Contribution Toward an Encyclopedia of, *Smithsonian Miscellaneous Collections*, 119
Insect and Plant-growth Substances Reciprocal Effects of (Dr D B Carlisle et *al*), 1230
Insect Cells Chemical Nature of the System controlling Gene Activities in (Dr H Kroeger), 1234
Insect Physiology Advances in, Vol I (edited by J W L Beament et *al*), *review* by Prof J W S Pringle, 507
Insect Senses Physiology of (Prof V G Dethier), *review* by Prof V B Wigglesworth, 974
Insecticide Resistance in the Cabbage Root Fly in Britain (T H Coaker, D J Mowat and G A Wheatley), 664
Insecticides on Malaria Vectors Deterrent Effect of (Dr J de Zulueta and J R Cullen), 860 , (A Smith), 860
Insecticides related to the Active Metabolite of Tri-*o*-cresyl Phosphate New (M Eto et *al*), 171
Institut pour l'Encouragement de la Recherche Scientifique dans l'Industrie et l'Agriculture, Rapport Annuel, Exercice 1962, 24
Institute of Applied Science of Victoria, report for 1962, 216
Institute of Electrical and Electronics Engineers Formation and election of Officers, 118
Institute of Linguists *Preparations for an International Conference*, 217
Institute of Medical and Veterinary Science, Adelaide, twenty-fourth annual report, 406
Institute of Metallurgists *Metallurgy—Paths to Qualification*, 406
Institute of Physics and the Physical Society Conference on "The Liquid State" (Prof J S Rowlinson and Dr E R Buckle), 742
  Problems Facing University Physics Departments, 200
  Problems Facing University Physics Departments a Report prepared by a committee appointed by the Council of the Institute, 298
  Publications, 523
Institute of Personnel Management (T H Hawkins), 1272
Institute of Radiology Meeting, 120
Institution of Mining and Metallurgy, President for 1963, 317
Institution of the Rubber Industry Awards for 1963, 837
"Instrumentation and Control—Does it Pay ?" One day symposium organized by the Society of Instrument Technology—South Yorkshire Section, 23
Insulin of α-Amino-isobutyric Acid Transport in the Absence of Protein Synthesis *In vitro* Stimulation by (Dr G R Fritz and Prof E Knobil), 682
Integration at an Inhibitory Interneurone Inhibition of Renshaw Cells (Prof V J Wilson and Dr W H Talbot), 1325
Intelligence An Ante-natal Determinant of (J E Orme), 1239
Intensity of Neutral Argon Emission Lines radiated by the Low-voltage-High-amperage Arc compared with Four High-voltage Type Arcs (C Mitchell), 1194
Interaction between Calcium Carbonates and Bentonite Suspensions (Dr N Lahav and G H Bolt), 1343
Interaction of Science and the State, 197
Interdiffusion Method for the Preparation of Single Crystals of Certain Hydroxides and Basic Salts (Y M de Haan), 876
Interfacial Phenomena (Prof J T Davies and Prof E K Rideal), second edition, *review* by N K Adam, 1140
Interference between Polioviruses and the Effect of Ultra-violet Light (Dr M L Fenwick), 1129
Interferometric Means Measurement of Surface Tension by (Dr B S Thornton), 1000
Interferon Density Homogeneity and Estimated Molecular Weight of (L E Kreuz and Prof A H Levy), 883
Interferon Production by 'Active' and 'Inactive' Chikungunya Virus in Chick Cells Effect of Actinomycin D on (Dr G E Gifford and Dr E Heller), 50
Interferon Responses of Chick Embryo Fibroblasts to Nucleic Acids and Related Compounds (Dr K E Jensen, A L Neal, R E Owens and Dr J Warren), 433
Interferon Yield with Multiplicity of Infection Variation of (Dr G E Gifford), 91
Intergroup Selection in the Evolution of Social Systems (Prof V C Wynne-Edwards), 623
Inter-industrial Oceanographic Research in the United States (M J Tucker), 411
Intermediary Metabolism in the Immature Liver Fluke, *Fasciola hepatica* L (Dr J P G Williams and Dr C Bryant) 489
Intermolecular Energy Transfer Spin-orbit Coupling and (Dr R F Vassil'ev), 773
Internal Sedimentation Structures of Well-washed Sands and Sandstones in Relation to Flow Conditions (J R L Allen), 326
International Academy of Astronautics Election of President and Committee Members, 218
International Association of Meteorology and Atmospheric Physics, meeting in 1964, 1268
International Association of Microbiological Societies Symposium on "The Characterization and Uses of Human Diploid Cell Strains" (L Hayflick et *al*), 1161
International Association of Seismology and Physics of the Earth's Interior Dr J H Hodgson elected President, 120
International Bureau of Time Uniform Time and Constant Frequency for the Year 1964, 1050
International Commission on Zoological Nomenclature, 218
International Conference Preparations for an (Institute of Linguists), 217
International Council of Scientific Unions Election of Officers, 1052
International Review of Neurobiology, Vol 4 (edited by Carl C Pfeiffer and John R Smythies), *review* by Prof J N Cumings, 395
Interneurone Integration at an (Prof V J Wilson and Dr W H Talbot), 1325
Inter-ocular Transfer of Movement After-effects during Pressure Blinding of the Stimulated Eye (H B Barlow and Dr G S Brindley), 1347
Interrenal and the Corpuscles of Stannius of *Anguilla anguilla* and *Conger conger* Histochemical Reaction for Steroid-3β-ol-dehydrogenase in the (Prof G Chieffi and V Botte), 793
Interstellar Medium Radio Observations of OH in the (Dr S Weinreb et *al*), 829
Intestinal Alkaline Phosphatase Heterogeneity of Human (Dr D W Moss), 1206
Intestines of the Desert and Migratory Locusts Some Differences in the Passage of Food through the (Dr D Goodhue), 288
Intradermal Injection of Rare Earths Skin Reaction to (Prof T J Haley and H C Upham), 271
Intraventricular Sodium Seizures Induced by (Prof G H Glaser and G Wolf), 44
Introduction to Advanced Electrical Engineering (C Jones), *review* by Prof A H M Arnold, 819
Introduction to Plasma Physics (Dr W B Thompson), *review* by J Cooper, 962
Introduction to the Biochemistry of the Cancer Cell (Harris Busch), review by Prof F Bergel, 301
Introduction to Waves, Rays and Radiation in Plasma Media (Dr J J Brandstatter), *review* by J Cooper, 962
Inventing the Future (Prof Dennis Gabor), *review* by Prof C H Waddington, 983
Invertebrates Mucus in, 946
Investigation of Non-recurring Phenomena The Research Cinema Film (E R. Sorenson and Dr D C Gajdusek), 112
In vitro Cell Transformation with Chemical Carcinogens (Y Berwald and Prof L Sachs), 1182
In vitro Effect of Salicylate on Amino-acid Accumulation by Kidney Cortex Slices (Dr S Segal and A Blair), 139
In vitro Stimulation by Insulin of α-Amino-isobutyric Acid Transport in the Absence of Protein Synthesis (Dr G R Fritz and Prof E Knobil), 682
In vivo Destruction of Exogenously applied Indolyl-3-Acetic Acid as Influenced by Naturally Occurring Phenolic Acids (Dr M H Zenk and G Muller), 761
In vivo Incorporation of Tritiated Thymidine in Acute Leukæmia Chromosomes (Dr F Gavosto, A Pileri, L Pegoraro and A Momigliano), 807
Iodine-125, -131 or -132 Preparation of Very High Specific Activity Iododeoxyuridine, Iodouridine and Iodouracil, labelled with (D J Silvester and Miss N D White), 65
Iodine-131 in Biochemical Research Low-level Assay of (Dr C F Barnaby and Dr L G Plaskett), 950
Iodine in Marine Algae Mechanism for concentrating (Dr Z Lewitus and H. Schreiber), 893
Iodine Secretion in the Blood by the Thyroid Gland Precocious Organic (R Riviere et *al*), 682
Iododeoxyuridine, Iodouridine and Iodouracil, labelled with Iodine-125, -131 or -132 Preparation of Very High Specific Activity (D J Silvester and Miss N D White), 65
Iodouracil, labelled with Iodine-125, -131 or -132 Preparation of Very High Specific Activity Iododeoxyuridine, Iodouridine and (D J Silvester and Miss N D White), 65
Iodouridine and Iodouracil, labelled with Iodine-125, -131 or -132 Preparation of Very High Specific Activity Iododeoxyuridine, (D J Silvester and Miss N D White), 65
Ion Exchange Paper Chromatography Temperature as a Variable in (Dr C S Knight), 1314
Ion Exchange Resins to alter the Concentrations of Individual Inorganic Ions in Blood *in vivo* Use of (Dr M A Kumar and I McIntyre), 181
Ionization Coefficients in Helium at High Pressures (Dr J Dutton, Prof F Llewellyn-Jones and D B Rees), 58
Ionizing Radiations A Mechanism for the Direct Action of (Dr R Braams), 752
Ionizing Radiations on Cells Initial Effects of (edited by R J C Harris), *review* by Dr P J Lindop, 1036
Ionosphere over the Magnetic Equator Lunar Tides in the Equatorial Electrojet and in the (R G Rastogi), 1083
Ions Changes in the Constitution of Myelin caused by (Dr M Wolman and H Wiener), 886
Ions, Transport of, Across Membranes (Dr S Salminen, A Ekman, J Rastas and Dr S Salminen), 1069
Iron Dislocation Loops in Irradiated (B C Masters), 254
Iron Requirements for Nitrate Reductase in *Photobacterium sepia* Molybdenum and (Dr D J D Nicholas et *al*), 1125
Iron Samples in Relation to Tritium Content in Meteorites Diffusion of Tritium out of (H Dubost and Prof M Lefort), 566
Irradiated (600 R) Infantile Rats and Mice Recovery Effects of Homologous Testes DNA Injected into Total-Body (Miss N Savković), 1073
Irradiated Micro-organisms of Growth in the Presence of Acriflavine Effects on (T Alper), 534
Irzykiewicz, H , and Powning, R F Chitinase from the Gut of the Cockroach *Periplaneta americana*, 1128

Isaac, Prof P K Abnormally Divergent 'Sectors' in Cultures of Filamentous Fungi, 382
Isaacson, Prof R L, and Wickelgren, W O Effect of the Introduction of an Irrelevant Stimulus on Runaway Performance of the Hippocampectomized Rat, 48
Isakovic, Dr K, et *al* Effect of Neonatal Thymectomy, Bursectomy and Thymobursectomy on Hæmagglutinin Production in Chickens, 273
Isoallele Natural Selection on an (Dr L Van Valen and Dr L Levine), 1236
Isoantisera against Leukæmic and Thymic Lymphocytes Specificity of (Prof A E Reif and Dr J M V Allen), 1332
XO/X-isochromosome X Mosaic Human Female Autoradiographic Studies of *X*-Chromosome Duplication in an (O J Miller et *al*), 918
d-Isocitric Acid Enzymatic Evidence for the Configuration of (Prof A Meister and M Strassburger), 259
Isolation and Identification of Two Smooth Muscle Stimulants from Menstrual Fluid (Dr G Eglinton, Prof R A Raphael, Dr G N Smith Dr W J Hall and Dr V R Pickles), 960
Isolation of an Easily Precipitable α_1-Glycoprotein of Human Serum (Dr H E Schultze, K Heide and H Haupt), 1103
Isolation of Infectious Poliovirus Ribonucleic Acid from Supernatant Fluids after Ultracentrifugation (Dr O Tolbert and Dr R Engler), 498
Isolation of Louping ill Virus from the Red Grouse (Dr H Williams, H Thorburn and G S Ziffo), 193
Isolation of Maltotriose and Maltotetraose from Starch Hydrolysates (A G Clark and K R L Mansford), 30
Isolation of Nuclei from Avian Erythrocytes by Partial Electrocytolysis (B R A O'Brien), 1219
Isomerism on the Behaviour of *cis* and *trans* Hexahydroindanes under Electron Impact Effect of Geometrical (P Natalis), 881
Isoprenoids Radiolysis of (W E Shelberg et *al*), 754
2-Isopropylthiamorpholin-3-one-5-carboxylic Acid Preparation of (S Mizuhara et *al*), 678
Isotope Redistribution Reactions Kinetics of (H Bolder et *al*), 1316
"Isotopes" the Fiftieth Anniversary, 833
Isovalthine Configuration of Urinary, (S Ohmori et *al*), 678

New Zealand Report of the Department of Scientific and Industrial Research for 1962-63, 1161
Nicholas, Prof D J D Appointed to the Waite chair of agricultural biochemistry, 406
Nicholas Dr D J D , *et al* Adenosine Triphosphate-dependent Reduction of Nicotinamide Adenine Dinucleotide by Ferrocytochrome c in Chemoautotrophic Bacteria, 759
  Molybdenum and Iron Requirements for Nitrate Reductase in *Photobacterium sepia*, 1125
  Nitrogen Fixation in Cell-free Extracts of *Azotobacter vinelandii* prepared by Lysis with Phage A22, 709
Nicholls, D G , and Ling, J K Immobilization of Elephant Seals using Succinylcholine Chloride, 1021
Nichols, Dr D , and Ager, Dr D V Marine Ecology and Palæoecology, 942
Nicholson Dr A N , and Turner, E A Mesial Surface of the Brain and Genital Function, 788
Nicholson J S , et *al* Some Biological Properties of 'Ibufenac', a New Antirheumatic Drug 271
Nickel—Cadmium System Equilibrium Diagram for the (R J Lott and J K. Critchley) 773
Nickel, 25 per cent Niobium Stabilized Austenitic Steel by Irradiation with Thermal Neutrons Elevated Temperature Embrittlement induced in a 20 per cent Chromium (A C Roberts and D R Harries), 772
Nicotiana glutinosa infected by Tobacco Mosaic Virus Nicotinamide Adenine Dinucleotide and Nicotinamide Adenine Dinucleotide Phosphate Concentration in Leaves of (D W Sunderland and M J Merrett), 921
Nicotinamide Adenine Dinucleotide and Nicotinamide Adenine Dinucleotide Phosphate Concentration in Leaves of *Nicotiana glutinosa* infected by Tobacco Mosaic Virus (D W Sunderland and M J Merrett), 921
Nicotinamide Adenine Dinucleotide by Ferro-cytochrome *c* in Chemoautotrophic Bacteria Adenosine Triphosphate-dependent Reduction of (Dr M I H. Aleem et *al*), 759
Nicotinamide Adenine Dinucleotide-levels Effect of Injection on (Miss R Yasin and Prof F Bergel), 783
Nielsen, K F , and Cunningham, R K Evidence against Relationships between Root Cation Exchange Capacity and Cation Uptake by Plants, 1344
Night Sky in November, 120 , December, 634 , January, 1155
Nikolsky, G V The Ecology of Fishes, *review* by Dr R H McConnell, 102
Nikolsky, Dr N N , and Krolenko, Dr S A Distribution of Cyanole and Neutral Red in the Giant Axon of the Squid, 280
Nilan, Prof R A , et *al* Effects of *n*-Butyl Methanesulphonate and Related Mutagens on Barley, 714
Nimeck, Dr M W , et *al* Nitrogen Fixation in Cell-free Extracts of *Azotobacter vinelandii* prepared by Lysis with Phage A22, 709
Ninhydrin-Schiff Reaction with Copper Ions Blocking the (Dr Gy Rappay), 274
Nishi, S , et *al* Effect of Calcium Ions on Prolonged Action Potentials and Hyperpolarizing Responses, 786
Nishimura, Dr K , et *al* Mechanisms for the Decrease of Brain Serotonin, 578
Nitrate Fluorescence Spectrum of Di-cæsium Uranyl (R K Asundi and R M Dixit), 668
Nitrate Reductase in *Photobacterium sepia* Molybdenum and Iron Requirements for (Dr D J D Nicholas et *al*), 1125
2-Nitro-1-phenyl-1-phenylthioalkanes Antifungal Activity of Some (Dr N G Clark et *al*), 171
Nitrogen Liberation of Extracellular Nitrogen by Two Nitrogen-fixing Blue-green Algae (Dr W D P Stewart), 1020
Nitrogen Dioxide (NO_2) Magnetic Effects in the Far Infra-red Spectrum of (Dr H A Gebbie et *al*), 1304
Nitrogen Fixation in Cell-free Extracts of *Azotobacter vinelandii* prepared by Lysis with Phage A22 (Dr M W Nimeck, Dr P W Wilson and Dr. D J D Nicholas), 709
Nitrogen Mustard Resistance of Phytohæmagglutinin-treated Lymphocytes to X-rays and (Dr R Schrek and Dr S Stefani), 482
Nitrogen Mustard on Erythrocyte Acetylcholinesterase Effect of (P C Vincent et *al*), 1110
Noback, Dr C R , and Masurovsky, Dr E B Changes in the Esterases of Rat Brain and Blood Serum Following Acute Cranial Exposure to X-rays, 847
Nobel Peace Prize awarded to Prof L Pauling, 218
Nobel Prize for Medicine, 1963, 314
Nobel Prize for Physics and Chemistry, 1963, 631
Nobert test plate and a Grayson rulings (G L'E Turner), 837
Noise Transport and Traffic (Dr G M L Gladwell), 839
Nolan, P D , and Jee, W S S Origin of Osteoclasts from the Fusion of Phagocytes, 225
Nolte, Dr D J A Pheromone for Melanization of Locusts, 660
Nomographic Computation of Complicated and Highly Saturated Magnetic Circuits (Prof Otto Benedikt), *review* by E M Freeman, 1251
Non-climatic Factors affecting the Shape of Apple Fruits (Prof M N Westwood and L T Blaney), 802
Non-colonizing Aphid Vector of Potato Virus Diseases (A R Edwards), 1233
Non-random Distribution of Bull Spermatozoa in a Drop of Sperm Suspension (Dr A D Maude), 381 , (Lord Rothschild), 381
Norbert, G F , et *al* Lactic Dehydrogenase in *L*1210 Cells, 903
Nord, F F (edited by) Advances in Enzymology and Related Subjects of Biochemistry, *review* by Dr T Mann, 972
Nordon, P Forced Convective Mass Transfer in Absorption and Desorption, 1065
Norepinephrine-levels and Reserpine Antagonism in Mice Elevation by Propynylamines of Rat Tissue (Dr J R McLean and Dr G Chen), 686
Norman, Prof A G , et *al* A Glass Micro-bead System for the Investigation of Soil Micro-organisms, 1227
Normansell, Dr D Appointed to a Research Fellowship in Pathology, 317
Norrish, Prof R G W , and Heyrovsky, M Photovoltaic Phenomena in Aqueous Solutions, 880
North American Crust Age of the (Dr W F Slawson et *al*), 413
Novikova, M N , et *al* Transformation of Hæmopoietic Cells of Bone Marrow Allografts into Lymphocytes in X-irradiated Dogs, 1170
Nuclear Instruments Proceedings of the Symposium on, September 1961 (edited by J B Birks), *review* by Dr T E Allibone, 1136
Nuclear Instruments and Their Uses Vol I (edited by Arthur H Snell), *review* by Dr T E Allibone, 1136
Nuclear Magnetic Resonance of the Copper-63 and Copper-65 Nuclei in a Single Crystal of Copper Ultrasonic Excitation of (D J Barnes), 253
Nuclear Reactors Magneto-Hydrodynamic Generation and (J K Wright), 948
  Monitoring of Sea-Water for Important Radioisotopes Released by (Dr. N Yamagata and K Iwashima), 52
Nuclear Studies The Casaccia Centre for, 529
Nucleated and Non-Nucleated Cells in Normal Rat Bone Marrow Sedimentation Properties of (Prof H C Mel), 423
Nucleation of Gypsum Crystals (M J Ridge and H Surkevicius), 1089
Nucleic Acids and Related Compounds Interferon Responses of Chick Embryo Fibroblasts to (Dr K. E Jenson et *al*), 433
"Nucleic Acids–Structure, Biosynthesis and Function", symposium will be held, 525
Nucleic Acids with Streptomycin and Dihydrostreptomycin Differences in Precipitability of (Prof M Moskowitz) 335
Nuclei from Avian Erythrocytes by Partial Electrocytolysis Isolation of (B R A O'Brien), 1219
Nucleolochromosomal Apparatus of Animal Cells Biosynthesis of Messenger and Ribosomal Ribonucleic Acids in the (G P Georgiev et *al*), 1291
Nucleophilic Substitution at a Saturated Carbon Atom (Dr C A Bunton), *review* by Prof N B Chapman, 973
Nucleosides Inhibition of the Aggregation of Blood Platelets by (Sonia Clayton *et al*), 138
Nuffield, Lord *Obituary* by Dr J W McAnuff, 312
Nuffield Foundation, 1962–1963 505 526
Nuffield Foundation Science Teaching Project *Progress Report*, 633
Nuffield Unit of Medical Genetics at the University of Liverpool 735
Number of Cells developed during the Life-time of a Thunderstorm (Prof S V C Aiya and B S Sonde), 562
Number of Items presented and recalled as Determinants of Short-term Recall (L K Selzer and Prof W A Wickelgren) 1239
Nutman P S , and Mosse, Barbara (edited by) Symbiotic Associations, *review* by Dr P H A Sneath, 1253

Nutrition and Allied Sciences Progress in (Rowett Research Institute), (edited by D P Cuthbertson), *review* by Prof A M Copping, 201
Nutrition Foundation, Swedish Mild-Moderate Forms of Protein-Calorie Malnutrition, Symposia of the, 1962 *review* by Prof J Yudkin, 724
Nyburg, S C , and Halliwell, H F Negative Degrees of Freedom and the Phase Rule, 670
Nydal, R Increase in Radiocarbon from the most recent series of Thermonuclear Tests, 212
Nylon 66 Action of Polar Reagents on (G Sarda and Dr N Peacock), 67

OBESE-hyperglycæmic Mice Glycerolkinase Activity in White Adipose Tissue of (D H Treble and J Mayer), 363
O'Brien, B R A Isolation of Nuclei from Avian Erythrocytes by Partial Electrocytolysis, 1219
O'Brien, C A , et *al* Multiple Anomalies occurring in a New-born Spanish Goat following Prenatal Gamma-radiation, 906
O'Brien, E , and Seeman, Dr P M Sodium-Potassium-activated Adenosine Triphosphatase in Schizophrenic Erythrocytes, 263
O'Brien, Dr J R Some Effects of Adrenaline and Anti-Adrenaline Compounds Platelets *in vitro* and *in vivo*, 763
Observations of the *Zeta* Spectrum in the Wavelength Range 16 Å-400 Å (B C Fawcett, A H Gabriel, W G Griffin, B B Jones and R Wilson), 1303
Observed Triplication of *PKP* (Dr R D Adams and M J Randall), 744
Occultation of the Crab Nebula by the Solar Corona in June 1963 (J D Wyndham and B G Clark), 766
Occurrence of Indole Compounds containing Phosphorus in Etiolated Pea Seedlings (Dr E Koves and Dr F Sirokman), 910
Occurrence of *neo*-Inositol Hexaphosphate in Soil (D J Cosgrove and M E Tate), 568
Oceanographic Research in the United States Inter-industrial (M J Tucker), 411
Oceanopapaver The Genus (Dr R H Manske), 1123
Octacalcium Phosphate and Hydroxyapatite Structures Similarity of (Prof D R Taves), 1312
Octachloronaphthalene Conformation of (Dr G Gafner and Dr F H Herbstein), 130
Odell, Dr Peter R An Economic Geography of Oil, *review* by H B Milner, 992
Œstrogens on Augmented Activity of Endometrial Carbonic Anhydrase caused by 4,4-Methylenedianiline Inhibitory Effects of (Dr K Yamashita), 81
Ohmori, S , et *al* Configuration of Urinary Isovalthine, 678
  Preparation of 2-Isopropylthiamorpholin-3-one-5-carboxylic Acid, 678
Oil An Economic Geography of (Dr Peter R Odell), *review* by H B Milner, 992
Oil and Colour Chemists' Association sixteenth technical exhibition, 409
Oil Film Thickness under Elasto-hydrodynamic Lubrication Optical Measurement of (R Gohar and Dr A Cameron), 458
Oil, How much Resources of Petroleum (H B Milner), 223
Oils Derived from Coal Optical Activity in (C Zahn et *al*), 53
Ojeda, Dr A , et *al* Basis for the Antigenicity of Hapten-Poly-L-Lysine Conjugates in Random-bred Guinea Pigs, 544
Okano, S , et *al* Additive Effect of Sub-Threshold Concentrations of some Organic Compounds Associated with Food Aromas, 1288
O'Kelly, J , *et al* Toxicity and Fluorescence Properties of the Aflatoxins, 1101
Oki, Y , et *al* Some Effects of Chlorpromazine on the Activity of Pig Serum Cholinesterase, 361
Olduvia Gorge, Tanganyika Magnetization of Basalt of Bed I, (Dr C S Gromme and Prof R L Hay), 560
Oliveira, A , et *al* Fundamental Function of Ac-globulin and Lipid in Blood Clotting, 1014
Oliver and Boyd Two-day meeting of editors of British Geological Journals, 739
Oliver, Prof W T , et *al* Some Effects of Chlorpromazine on the Activity of Pig Serum Cholinesterase, 361
Olivocochlear Fibres in the Cat Function of the Uncrossed Efferent (Prof J E Desmedt and Dr V LaGrutta), 472
Öner, N , and Tekman, S A Pentose identified in the Carbohydrate Group of Spongin, 77
Optical Activity in Oils Derived from Coal (C Zahn, S H Langer, B D Blaustein and I Wender), 53
Optical Brightness of the West Ford Experiment (W Liller), 349
Optical Measurement of Oil Film Thickness under Elasto-hydrodynamic Lubrication (R Gohar and Dr A Cameron), 458
Optical Society of America The Frederic Ives Medal Award, 525
Oral Feeding with Dimethylbenzanthracene Effect of 2-Methyl-1,2-*bis*-(3-pyridyl)-1-propanone (Metyrapone) on the Production of Mammary Tumours induced in Rats by (J E Helfenstein and Dr S Young), 1113
Orchid Endophytes Production of Pectic Enzymes by *Rhizoctonia solani* and (Dr G Hadley and M Perombelon), 1337
Ord, Dr M G , and Stocken, Dr L A Biochemical Effects of X-Irradiation and the Sulphydryl Hypothesis A Re-Appraisal, 136
Organic Chemistry Dr G I Fray appointed lecturer in, 837
  Dr J S Littler appointed lecturer in, 837
  Dr C W Rees appointed reader, in 317
  Textbook of (Prof Alexander Gero), *review* by H Dunnicliff, 1254
Organic Chemistry, Vol I (I L Finar), fourth edition, *review* by Dr G L Buchanan, 303
Organic Chemistry (Dr D J Waddington), *review* by H Dunnicliff, 970
Organic Chemistry Laboratory Operations (W B Renfrow and P J Hawkins), *review* by D C Firth, 724
Organic Compounds Spectrometric Identification of (Dr Robert M Silverstein and Dr G Clayton Bassler), *review* by Dr D T Lewis, 989
Organic Compounds Associated with Food Aromas Additive Effect of Sub-Threshold Concentrations of Some(D G Guadagni et *al*), 1288
Organic Compounds from Food Odours by Pyrolysis Identification of (J. H. Dhont), 882
Organic Crystals Surface Conduction in Volatile (Prof D D Eley et *al*), 255
Organic Glasses at 77°K Electron Spin Resonance Evidence of Radiation-induced Electrons trapped in (Dr C Chachaty and Dr E Hayon), 59
Organic Liquids and Solids due to Excitation by High d c Fields Light Emission from (Dr M Darveniza), 558
Organic Matter and Soil Productivity (A M Smith), 222
Organic Radical Reaction, New, involving No Free Valence (M B Neiman, E G Rozantzev and Yu G Mamedova), 256
Organization for Economic Co-operation and Development Ministerial Meeting on Science Agenda Item III (Background Paper)–*Science Economic Growth and Government Policy*, 719
Organization for Economic Co-operation and Development *Science and the Policies of Governments*, 22
Organization for Economic Co-operation and Development, *Science and the Policies of Governments The Implications of Science and Technology for National and International Affairs*, 199, 719
Organization of Science by Scientists, 216
Organizational Choice (E L Trist, G W Higgin, H Murray and A B Pollock), *review* by T H Hawkins, 6
Origin of Methanol and Dimethyl Sulphide from Cooked Foods (J C Casey, R Self and T Swain), 885
Origin of Osteoclasts from the Fusion of Phagocytes (W S S Jee and P D Nolan), 225 , (E A Tonna), 226
Origin of Races (Carleton S Coon), *review* by Dr G Ainsworth Harrison, 1033
Origin of Sodium Concentration Profile in the Renal Medulla (Dr G G Pinter and Dr J L, Shohet), 955
Orme, J An Ante-natal Determinant of Intelligence, 1239
Ornithosis in the Wood Pigeon Occurrence of (D A Haig and A McDiarmid), 381
Orr, Lord Boyd Man and his Future, *review*, 302
Orr, jun , Prof C , et *al* Particle Size Classification by Adhesion, 360
Orr, jun , Prof C , and Keng, E Y H Light Boundary Effect in Photophoresis, 352
Orris, L , et *al* Tumour-enhancing Activity of the Active Principles of *Croton tiglium* L , 1115
Ørskov, F , et *al* Acidic Polysaccharide Antigens of a New Type From *E coli* Capsules, 144
Ørskov I , et *al* Acidic Polysaccharide Antigens of a New Type From *E coli* Capsules, 144
Orthogonal Diameters in the Analysis of Muscle Fibre Size and Form (S K Song, N Shimada and Dr P J Anderson), 1220
Oryctolagus cuniculus (L), on a Sub-Antarctic Island Reproduction in a Free-living Population of Domestic Rabbits, (E Shipp et *al*), 858
Oryx 7 Nos 2 and 3, 1963, 633
Osborn, Fairfield (edited by) Our Crowded Planet, *review* by Prof L Dudley Stamp, 983
Osborne, D J , et *al* Reciprocal Effects of Insect and Plant-growth Substances, 1230
Osborne, D J , and Moss, S E Effect of Kinetin on Senescence and Abscission in Explants of *Phaseolus vulgaris*, 1299
Oscillatory Experiments with a Cone-and-plate Viscometer (Dr K Walters), 458
Oshima, Y , et *al* Saligenin Cyclic Methyl Phosphate and its Thiono Analogue New Insecticides related to the Active Metabolite of Tri-*o*-cresyl Phosphate, 171
Osman Hill, Dr W C *Obituary* of Dr Annie Porter, 21
Östberg, G Boron Constituents in Low-boron Steel, 1311
Osteoclasts from the Fusion of Phagocytes Origin of (W S S Jee and P D. Nolan), 225 , (E A Tonna), 226
Osteon of the Cat Maturation Rate of the (J D Manson and N E Waters), 489
Osterberg, Prof C , et *al* Acceleration of Sinking Rates of Radionuclides in the Ocean, 1276
Ostic, Dr R G , et *al* Age of the North American Crust, 413
O'Sullivan, Dr D G , and Wallis, A K 2-(α-Hydroxybenzyl)-benzimidazolium Salts and their Influence on Cultured Cells infected with Poliovirus, 1101
Oswin, H G , *et al* A Direct Hydrocarbon/Air Fuel Cell, 256
Othmer, Kirk Encyclopedia of Chemical Technology, Vol 1, second edition, *review* by W D Maniece, 824
Ottewill, Dr R H , and Haydon, Dr D A Mechanisms of Adsorption from Solution, 1157
Oundle School Natural History Society, Annual Report, 407
Our Crowded Planet Essays on the Pressures of Population (edited by Fairfield Osborn), *review* by Prof L Dudley Stamp, 983
Our Developing World (L Dudley Stamp), *review* by Prof Emrys Jones, 723
Ovary Development in Mosquitoes (Dr B R Laurence and M A Roshdy), 495
Overhauling Britain's Science Machinery, 1029
Overseas Broadcasting and International Understanding, 391
Oversowing Pasture Legumes into the *Hyparrhenia* Grassland of Northern Rhodesia (C A Smith), 811
Ovine Prolactin Preparation of a Low Molecular Weight Component with Lactogenic Activity from a Limited Chymotryptic Digest of (Dr M Sluyser and Prof Choh Hao Li), 1007
Oviposition in Relation to the Accumulation of Bloodthirsty Black Flies (*Simulium* (*Gnus*) *articum* Mall (Diptera) Prior to a Damaging Outbreak (F J H Fredeen), 1024
Oviposition on Dry Surfaces by *Anopheles* (*Cellia*) *gambiae* Giles (L K H Goma), 1232
Owen, Prof P R *Obituary* of Sir Leonard Bairstow, 403
Owens, R E , et *al* Interferon Responses of Chick Embryo Fibroblasts to Nucleic Acids and Related Compounds, 433
Owens, R S , ard Roberts, R W Titanium Lubrication, 357
Ox Pituitary Growth Hormone Fractions Comparison of *in vivo* and *in vitro* Actions of Various (Dr K L Manchester and M Wallis), 888
Oxalacetic Acid in Water—Ethanol Mixtures Metal-ion-catalysed Decarboxylation of (Rev G W Kosicki and S N Lipovac), 359
Oxidation Proposed Method for Observing the Effect of Electric Fields on (A T Fromhold, jun) 559
Oxidation Kinetics Uhlig Model of (A T Fromhold, jun), 1309
Oxidative Phosphorylation and Related Processes (Dr M R Atkinson and the late Prof R K Morton) 221
Oxide Films on Metals as revealed by Work Function Measurements Nature of Thin (C M Quinn and Dr M W Roberts), 648
Oxo-Compounds Inorganic Adduct Molecules of (Ingvar Lindqvist), *review* by Dr G W A Fowles, 969
Oxygen Depletion of a Limited Reservoir by Human Conjunctiva (Prof R M Hill and I Fatt), 1011
Oxygen Diffusion Rates and Nematode Movement in Cellulose Sponges (S D Van Gundy and Dr L H Stolzy), 1187
Oxygen in Tungsten and some other Transition Metals Diffusion of (A J Jacobs), 1310
Oxygen Isotopic Fractionation in the Water of Crystallization of Gypsum (Dr. R Gonfiantini and J C Fontes), 644
Oxygen Ring Compounds Naturally Occurring (Dr F M Dean), *review* by Dr R Livingstone, 509
Oxygen Saturation Hyperlipidæmia a Cause of Decreased (Prof G D Talbott and Prof R Frayser), 684
Oxytetracycline Accumulation in the Cells of Multiple Drug-resistant *Escherichia coli* Disappearance of (K Izaki and K Arima), 384
Oxytretracycline Relevant to its Bactericidal Action in the Cells of *Escherichia coli* Accumulation of (K Arima and K Izaki), 192
Oyama, V I Use of Gas Chromatography for the Detection of Life on Mars, 1058
Oyvin, Dr I A , *et al* Influence on Capillary Permeability of Lymph discharged from a Scald, 270

PACHOLCZYK, A G Faraday Rotation Effect in Extragalactic Radio Sources, 765
Painter Dr T J , et *al* Three New Trisaccharides obtained from Human Blood-Group A, B, H and Le^{a} Substances . Possible Sugar Sequences in the Carbohydrate Chains, 532

Pal, Dr P R Effect of Vitamin B$_6$ and its Analogues on the Swelling of Rat Liver Mitochondria, 173
Palæoecology Marine Ecology and (Dr D V Ager and Dr D Nichols), 942
  Pennsylvanian (Prof F H T Rhodes), 324
  Principles of (Darek V Ager), *review* by Dr G Y Craig, 1035
Palæomagnetic Indications of an Increase in the Earth's Radius (Dr D Van Hilten), 1277
Palæontology Dr T Barnard appointed Professor, of 317
Pancreatic Function in Hypothermia, (Dr P V Veghelyi, Dr T T Kemény, Dr A T Zsinka, Dr N Faur), 478
Pancreatic Phospholipase *A* on Lipoprotein-bound Phospholipids Action of Bovine and Human (E Condrea *et al*), 1096
Pannacciulli, Dr I , et *al* Glucose-6-phosphate and 6-Phosphogluconic Dehydrogenase Activities in the Red Blood Cells of Several Animal Species, 372
Pantin, Prof C F A , appointed chairman of the Trustees of the British Museum (Natural History), 634
Paper Detecting Fingerprints on (Dr R L Grant et *al*), 1348
Paper Chromatography Quantitative Analysis of Ketosteroids by Means of (R Stupnicki and E Stupnicka), 165
  Temperature as a Variable in Ion-exchange (Dr C S Knight), 1314
Papillary Damage in Experimental Animals Phenacetin-induced (C Abrahams *et al*), 695
Papillomembrana sp , A new Fossil, from the Upper Precambrian of Norway (Dr N Spjeldnæs), 63
Paraffin Sections of Monkey Spinal Cord by Indirect Immuno-fluorescence Visualization of Poliovirus Type III in (E Kovacs et *al*), 497
Paraprotein-producing Leukæmia and its Relation to Other Virus-induced Leukæmias Evidence of Murine, Virus-induced, (Dr R Rask-Nielsen), 440
Parasitology Advances in, Vol I (edited by Dr Ben Dawes), *review* by Dr G Lapage, 103
Parisi, M N , et *al* Effect of Antidiuretic Hormone on Permeability of Single Muscle Fibres, 365
Parker, Dr C A Delayed Fluorescence of 3 4-Benzpyrene Solutions, 331
Parker, Prof F S Attenuated Total Reflectance Spectra of Glycyl-L-alanine in Aqueous Solutions, 1093

Pritchard, Prof R H Appointed to the chair of Genetics, 834
Probe for Continuous Determination of Anæsthetic Chemical Potential *in vivo* (Dr J A Parsons), 1286
Problems Facing University Physics Departments (The Institute of Physics and the Physical Society), 200
Problems of Economic Growth (Prof C F Carter) (Substance of an evening discourse delivered at the British Association meeting), 210
Proceedings of the 1962 International Conference on High-Energy Physics, *review* by S Weintroub, 99
Proceedings of the International School of Physics "Enrico Fermi", Varenna, Italy, Courses 14-17, *review* by S Weintroub, 300
Proceedings of the First International Congress on Diamonds in Industry, *review* by B W Anderson, 3
Proceedings of the Symposium on Electromagnetics and Fluid Dynamics of Gaseous Plasma New York, 1961, (edited by Jerome Fox), *review* by J Cooper, 962
Proceedings of the Symposium on Nuclear Instruments, Harwell, September 1961 (edited by J B Birks), *review* by Dr T E Allibone, 1136
Prodenia litura (F) induced by Radioactive Males Inhibitory Effect of L-Methionine-methyl-^{14}C on Oviposition by Females of the Cotton Leaf Worm (Prof A A Abdel-Malek), 604
Production of Acetylene from Coal, using a Plasma Jet (R L Bond, I F Galbraith, W R Ladner and G I T McConnell), 1313
Production of 6-Aminopenicillanic Acid by Dermatophytes (Dr J Uri, G Valu and I Bekési), 896
Production of Cardiac Arrest in Animals (Dr J Heid and Dr O Szekeley), 1104
Production of Hydrogen Atoms in Teeth by X-irradiation (T Cole and A H Silver), 700
Production of Pectic Enzymes by *Rhizoctonia solani* and Orchid Endophytes (Dr G Hadley and M Pérombelon), 1337
"Productivity in Research", symposium to be held, 837
"Productivity in the Next Five Years" (National Productivity Year Conference), 218
Programming and Non-numerical Analysis Advances in (D Michie), 641
Progress in Control Engineering, Vol I (edited by R H Macmillan, T J Higgins and P Naslin), *review* by Dr E M Deeley, 964
Progress in Nutrition and Allied Sciences Being a contribution marking the first fifty years of the Rowett Research Institute (edited by D P Cuthbertson), *review* by Prof A M Copping, 201
Progress of Cancer Research (Dr P Alexander, Dr I Hieger and A L Levene), 1043
Proline-activating Enzymes from some Plant Species Different Specificities of (P J Peterson and L Fowden), 148
Prolongation of Homograft Survival in Mice with Single Doses of *Cyclo*phosphamide (Dr M C Berenbaum and I N Brown), 84
Propagation Experiments at High Frequencies Surface Wave Aerial with Small Side-lobes for Low-angle (B MacA Thomas), 416
Propagation of Infectious Bovine Rhinotracheitis Virus in Monkey Kidney Tissue Culture Cells (Prof H Rouhandeh), 386
Propanol-Water Mixtures on the Reactivity of Wool Cystine Effect of (Prof. H Zahn and T Gerthsen), 785
Prophylactic Activity of Suramin Complexes in 'Surra'-(Trypanosoma evansi), (B S Gill and M N Malhotra), 285
Proposal for an Educational Research Council and some of its Implications (Prof R D'Aeth), 116
Proposed Method for Observing the Effect of Electric Fields on Oxidation (A T. Fromhold, jun), 559
Proprioceptive Origin of Parkinsonian Tremor (Dr H J Hufschmidt), 367

Propynylamines of Rat Tissue Norepinephrine-levels and Reserpine Antagonism in Mice Elevation by (Dr J R McLean and Dr G Chen), 686
Prosser, Dr G S Appointed to a Research Fellowship, 941
Prostaglandin E_1 on Tissues which respond to Bradykinin Action of (Dr E W Horton), 892
Protective Effect of Deep-Body Hypothermia on X-ray-induced Mitotic Aberrations of Regenerating Rat Liver (Dr M J Ashwood-Smith and Dr G F Leong), 46
Protective Effect of Killed Trypanosome Vaccines with Incorporated Adjuvants (P Johnson, R A Neal and D Gall), 83
Protein Individual and Sub-group Antigenic Specificity of Bence-Jones (Dr S Stein *et al*), 1180
Protein Hydration Proton Magnetic Relaxation and (O K Daszkiewicz *et al*), 1006
Protein Particles in Tumour Cells Aggregation of (A Bolognari *et al*), 809
Protein Synthesis *In vitro* Stimulation by Insulin of α-Amino-isobutyric Acid Transport in the Absence of (Dr G R Fritz and Prof E Knobil), 682
Protein Synthesis *in vitro* by Cycloheximide Inhibition of (Dr M R Siegel and Dr H D Sisler), 675
Protein utilizing Adenosine Triphosphate Generated from Phytate A Complete Intracellular Unit for Incorporation of Amino-acid into Storage (the late Prof R K Morton and J K Raison), 429
Proteins Alkaline Degradation of Cystine, Glutathione and Sulphur-containing (Dr F M Robbins and Dr J A Fioriti), 577
  Monomer–Dimer Forms of Bence Jones (Dr G M Bernier and Prof G W Putnam), 223
Proteins as an Aid in Identifying Fungi Starch-gel Electrophoresis of (B G Clare), 803
Proteins in Leaves Development of Chloroplasts and the Synthesis of (Dr M J C Rhodes and Prof E W Yemm), 1077
Protemnodon bicolor, with Reference to the Limitations in Accuracy of Identifying Human Chromosomes Biometrics of the Karyotype of (R C Moore and Dr G Gregory), 234
Proteolytic Activity of Growth Media Filtrates from Non-pathogenic Species of *Verticillium* (J A Leal, I G Acha and Dr J R Villanueva), 290
Proterozoic of the Canadian Shield Possible Metazoans from the Early (M J Frarey and D J McLaren), 461
Prothoracic Gland and Gregarious Behaviour in Locusts (Dr D B Carlisle and Peggy E Ellis), 603
Prothoracotropic Hormone of Locusts (Dr D B Carlisle and Dr P E Ellis), 496
Prothrombin Biosynthesis, Nature of Preprothrombinæmia in Vitamin K-deficiency (Dr H C Hemker *et al*), 589
Proton Magnetic Relaxation and Protein Hydration (O K Daszkiewicz, J W Hennel, B Lubus and T W Szczepkowski), 1006
Protozoa Influence of Time of Addition of Antibiotic on the *in vitro* Life of Rumen Holotrich (D B Purser and H H Weiser), 290
Proulx, Dr P R Bound Carnitine in Bovine Brain, 1210
Prouse, Dr W A *Obituary* of Prof J E P Wagstaff, 313
Pseudomonas fluorescens Absence of Ribonuclease from the Ribosomes of (H E Wade and H K Robinson), 661
Psychiatric Hospital Admissions Geomagnetic Parameters and (Prof H Friedman *et al*), 626
Psychiatry Prof M Hamilton appointed to the chair of, 405
'Psychogenetic Stress' and Autointoxication in the Honey Bee (R J Pence, R D Chambers and M S Viray), 930
Psychophysical Law Neural Effects and the (Dr H W Horeman , M Treisman), 1241
Psychotherapy A Study of Brief (D H Malan), *review* by Prof H J Eysenck, 1135
  Dependency in (Prof William U. Snyder), *review* by Prof H J Eysenck, 1135
  Therapist-Patient Expectancies in (Dr Arnold P Goldstein), *review* by Prof H J Eysenck, 1135
Pteridophytes The Morphology of (Dr K R Sporne), *review* by Dr J D Lovis, 104
Public Expenditure Appraisal and Control (edited by Alan T Peacock and D J Robertson), *review*, 724
Publicacoes Culturais, No 57, 736
Puffer Fish Poison Action of (K M Li), 791
Pullman A , and Pullman, Prof B Quantum Biochemistry, *review* by Dr A C Allison and R Mason, 1037
Pullman, Prof B , and Pullman, A Quantum Biochemistry, *review* by Dr A C Allison and R Mason, 1037
Pullman, B J Appointed to a Research Fellowship in Chemistry, 317
Pulps Quantitative Analysis by X-ray Diffraction from Flowing (R Carson), 419
Purdom, Dr C E Damage to Livestock from Radioactive Fall-out, 946
Purification and Analysis of Human Saliva Lysozyme (Dr J F Petit and Dr P Jollès), 168
Purification of an Erythrocyte-coating Polysaccharide from *Staphylococcus aureus* (Dr R J Jones), 593
Purine and Pyrimidine Nucleotide Sequences in the Molecule of Calf Thymus Deoxyribonucleic Acid Participation of (V Habermann), 782
Purser, D B , and Weiser H H Influence of Time of Addition of Antibiotic on the *in vitro* Life of Rumen Holotrich Protozoa, 290
Putnam, Prof F W and Bernier, Dr G M Monomer–Dimer Forms of Bence Jones Proteins, 223
Pyke, Dr M Analytical Methods for Pesticides, Plant Growth Regulators and Food Additives, Vol I, *review*, 971
α-Pyridil Molecular Configuration of Benzil and (I Bernal), 1318
Pyridine and its Derivatives, Part 3 (edited by Erwin Klingsberg), *review* by Dr R Hull, 989
Pyridine Nucleotide Transhydrogenase by Dicumarol Inhibition of (Prof J McGuire *et al*), 71
Pyrimidine Nucleotide Sequences in the Molecule of Calf Thymus Deoxyribonucleic Acid Participation of Purine and (V Habermann), 782
Pyrite-type and Related Compounds with Zero Spin Moment Electrical Properties of (Dr F Hulliger), 1064
Pyrogen and their Immunological Responses in Antitetanic Serum Production Correlation between the Reaction of Horses to a (L Chiosa *et al*), 286
Pyrolysis Identification of Organic Compounds from Food Odours by (J H Dhont), 882
Pyrolytic Graphite Small-angle Scattering by (R H Bragg *et al*), 555
Pyruvate, Diabetes and Starvation Citrate as an Intermediary in the Inhibition of Phosphofructokinase in Rat Heart Muscle by Fatty Acids, Ketone Bodies (P B Garland *et al*), 169
Pyruvate Metabolism in Mitochondrial Suspensions by Cobalt Inhibition of (J T Dingle and M Webb), 1208

QUANTITATIVE Analysis by X-ray Diffraction from Flowing Pulps (R Carson), 419
Quantitative Analysis of Ketosteroids by Means of Paper Chromatography (R Stupnicki and E Stupnicka), 165
Quantitative Chemical Micro-Analysis (Prof C J Van Nieuwenburg and J W L Van Ligten), *review* by Dr D T Lewis, 970
Quantitative Electrodeposition of Thorium and Uranium (W Parker, H Bildstein and N Getoff), 457
Quantitative Organic Analysis via Functional Groups (Dr S Siggia), third edition, *review* by P J Cooper, 969
Quantum Biochemistry (Prof B Pullman and A Pullman), *review* by Dr A C Allison and R Mason, 1037
Quantum Mechanics Mathematics for (Dr John David Jackson), *review* by Dr A L Stewart, 1252
Quantum Mechanics for Mathematicians and Physicists (Prof Ernest Ikenberry), *review* by Dr A L Stewart, 1252
Quantum Statistical Mechanics (Dr Leo P Kadanoff and Dr Gordon Baym), *review* by F J Smith, 1253
Quartz Fibres Transmission of Ultra-violet Rays in (Dr J Baskerville Hyde), 906
Quastel, Prof J H , and Sung, Dr Shan-ching X-irradiation of Deoxyribonucleic Acid, 781
Quaternized Sympathomimetic Amines (Prof J H Burn Dr M F Cuthbert and Dr R Wien), 270
Quayle, D B , and Smith, M Deoxyribonucleic Acids of Marine Mollusca, 676
Quayle, Dr J R Appointed Senior Lecturer in Biochemistry, 409
Queens University of Belfast New Department of Microbiology, 834
Quentin, M , *et al* A Simple Technique for the Isolation of β_1C(β_1A) Globulin, 262
Questionnaires Scaling and Personal (Dr J P N Phillips), 1347
Quick, Dr A J Anticoagulant Action of Adenosine Triphosphate, 469
Quiet Day Magnetic Variations near the Magnetic Equator (Dr K N Rao and Dr K S Raja Rao), 460
Quinine Dimorphism a Cardinal Determinant of Taste Sensitivity (Prof R Fischer and F Griffin), 343
Quinn, C M , and Roberts, Dr M W Nature of Thin Oxide Films on Metals as Revealed by Work Function Measurements, 648
Quinton, R M , and Halliwell, G Effects of α-Methyl DOPA and DOPA on the Amphetamine Excitatory Response in Reserpinized Rats, 178

RABBIT Appendix of the (O K Archer *et al*), 337
Rabbit Gamma-globulin Allotypes Immunochemical Analysis of (Dr A Feinstein *et al*), 653
Rabbit Serum Absence of Lysolecithin Formation in C'$_3$-deficient (I Haupt *et al*), 686
Rabbit Serum Amylase Electrophoretic Behaviour of (Prof J E Berk *et al*), 572
Rabbits (Domestic), *Oryctolagus cuniculus* (L), on a Sub-Antarctic Island Reproduction in a Free-living Population of (E Shipp *et al*), 858
Rabies Virus Effect of Ether on (Major R A Crandell and Capt W D Hillis), 715
Rabin, Dr B R Appointed reader in Biochemistry, 317
Race, Dr R R , *et al* The Xg Blood Groups of Negroes, 82 , *erratum*, 409
Rackis, J J , *et al* Mould Inhibitor in Soybeans, 1226
Radar Displays Man and (C H Baker) AGARDograph 60, *review* by C C Field, 394
Radcliffe, Prof S V , and Schatz, M Effects of High Pressure on the Strength and Structure of Martensites, 161
Radda, Dr G K and Calvin, Prof M Inhibition of the Photoreduction of Flavin Mononucleotide, 464
Radiation *Public Health Responsibilities in Radiation Protection* (World Health Organization Public Health Papers No 254), 524
Radiation-induced Changes in Cellular Proliferation, using a Double Labelling Autoradiographic Technique Studies of (Dr D R Davies and Dr D E Wimber), 229
Radiation-induced Hydrolysis of Acetal Evidence for the Reaction of H$_3$O$^+$ Ions in Spurs in the Radiolysis of Water (D R Smith and W H Stevens), 66
Radiation-induced Mutation Rates of Recessive Lethal Alleles in *Saccharomyces* Determination of (Dr W Laskowski and K Haefner), 795
Radiation Mortality through Magnetic Pre treatment Reduction of (Prof M F Barnothy), 279
Radiation of Wave-lengths less than 1 mm Generation Detection and Properties of Coherent (Dr M R Brown), 1270
Radiation Protection by Cysteamine and Cellular Sulphydryl Levels (Dr L Révész and Helena Bergstrand), 594
Radiation Protection Effect and Pharmacologically Changed Activity of the Reticulo-endothelial System (Dr K Flemming), 1117
Radioactive Decay of Antimony-124 (A Seshagiri Rao, V Lakshminarayana and Prof S Jnanananda), 750
Radioactive Fallout Damage to Livestock from (Dr C E Purdom), 946
Radioactive Fallout Short-lived Fission Products in Air and Rain (AERE-R4383), 1266
Radioactive Males Inhibitory Effect of L-Methionine-methyl-^{14}C on Oviposition by Females of the Cotton Leaf Worm *Prodenia litura* (F) induced by (Prof A A Abdel-Malek), 604
Radioactive Potassium in Smooth Muscle Influence of Duration of Experiment on Rate of Uptake of (H Bauer *et al*), 1104
Radioactivity in Drinking Water in the United Kingdom, 1962 *Results*, 940
Radio and International Geophysical Research (P A C Morris), 156 , Dr R L Smith-Rose), 156
Radio Astronomy and Space Science Frequencies for (Dr R L Smith-Rose), 18
Radiobiological Damage Possible Role of Copper Ions in (Prof M Anbar), 376
Radiocarbon from the most recent series of Thermonuclear Tests Increase in (R Nydal), 212
Radio Frequency Heating on Sperm Influence of (Dr D Makow and Dr H Grice), 1120
Radio Frequency Radiation from Cygnus Y (Dr H C Ko), 1193
Radioisotopes Released by Nuclear Reactors Monitoring of Sea-Water for Important (Dr N Yamagata and K Iwashima), 52
Radioisotopes, Use of, in Animal Biology and the Medical Sciences, Vol I (Proceedings of a Conference held in Mexico City, 1961), *review* by Dr K E Halnan, 203
Radiolysis of Gaseous Hydrogen Halides (R A Lee and Prof D A Armstrong), 552
Radiolysis of Isoprenoids (W E Shelberg and J F Pestaner), 754, (W E Shelberg, J F Pestaner and R Y Yahiku), 754
Radiolysis of Uranyl Nitrate Ketone Solutions Formation of Peroxidic Precipitate in the (J Teply and V Stulik), 671
Radionuclides in the Ocean Acceleration of Sinking Rates of (Prof C Osterberg *et al*), 1276
Radio Observations of OH in the Interstellar Medium (Dr S Weinreb, Prof A H Barrett, Dr M L Meeks and J C Henry), 829
Radiosensitivity, Comparative, of Animal Organisms and Copper Contents (Prof J Schubert), 375
Radiosensitivity of Human Liven Cells in Culture 6-Aminonicotinamide and the (Dr D L Dewey and Christine Hawes), 1176
Radio Sources of High Brightness Temperature Absorption in (P J S Williams), 56

Radio Spectroscopy Group , Autumn meeting "Generation, Detection and Properties of Coherent Radiation of Wavelengths less than 1 mm" (M R Brown), 1270
Radio Star and Satellite Scintillations (B H Briggs), 220
Radiotherapy A Fast-neutron Source for (D K Bewley), 701
Raga, F , and Manca, Dr P Thermal Dependence of the Absorption Band Edge in Zincblende-type Cadmium Sulphide obtained in Pressure Experiments, 874
Raghavachari, K V , et *al* Role of Free Radicals in the Photo-oxidation of Fe^{+2} in Acidic Solutions of Ferrocyanide, 163
Raison, J K , and the late Prof R K Morton Complete Intracellular Unit for Incorporation of Amino-acid into Storage Protein Utilizing Adenosine Triphosphate Generated from Phytate, 429
Raja Rao, Dr K S , and Rao, Dr K N Quiet Day Magnetic Variations near the Magnetic Equator, 460
Rakalska, Dr Z , and Juszkiewicz, Prof T Anti-œstrogenic Effects of Bovine Pineal Glands, 1329
Ramachandran, G N , and Srinivasan, R X-ray Intensity Statistics of a Pair of Related Crystals, 1090
Ramsauer Effect Anomalous Electron Scattering in Dilute Silver-Manganese Alloys and its Analogy with the (Dr M S R Chari), 875
Ramsay Memorial Fellowships Trust Fellowships for Advanced Students of Chemistry, 525 , Travel Grants, 525
Ramsay, Dr J G Awarded the Clough Award for 1963, 409
  Basic Problems in Geotectonics, *review*, 966
Rana, R S , and Jain, Dr H K Temperature Sensitivity of Chromosomes in Diploid and Polyploid Species of Wheat, 499
Randall, M J , and Adams, Dr R D Observed Triplication of *PKP*, 744
Randle, Dr P J Appointed to the chair of Biochemistry, 837
Randle, Dr P J , et *al* Citrate as an Intermediary in the Inhibition of Phosphofructokinase in Rat Heart Muscle by Fatty Acids, Ketone Bodies, Pyruvate, Diabetes and Starvation, 169
Random Distribution of Affected Birth Ranks in Anencephalic and Spina Bifida Sibships with Two Affected Cases (Dr S Milham, jun), 480
Rankine Lecture, the fourth, 941
Rao, A Seshagiri, et *al* Radioactive Decay of Antimony-124, 750
Rao, Dr A S , and Rao, M V Inoculum Potential and the Fusarial Wilt of Cotton, 598
Rao, Dr K N , and Raja Rao, Dr K S Quiet Day Magnetic Variations near the Magnetic Equator, 460
Rao, Dr M S , and Lokanadham, B Spectra of Meteor Wakes, 1194
Rao, M V , and Rao, Dr A S Inoculum Potential and the Fusarial Wilt of Cotton, 598
Rao, Dr V S R , and Foster, Prof J F Rotatory Dispersion Behaviour of Carbohydrates a Cotton Effect in D-Glucose, D-Xylose and Various Related Saccharides, 570
Raphael, Prof R A , et *al* Isolation and Identification of Two Smooth Muscle Stimulants from Menstrual Fluid, 960
Rapid Changes in Transpiration in Plants (Prof O V S Heath), 190 , (Dr H Rufelt), 191 , (Dr H Meidner and Prof O V S Heath), 283 , (H Rufelt), 284
Rapid Method for Determining Phytase Activity of Soil Micro-organisms (M P Greaves, G Anderson and D M Webley), 1231
Rapid Method for Determining the Corrosivity of the Atmosphere at any Location (D P Doyle and H P Godard), 1167
Rapoport, Prof S , and Egger, E Role of Non-covalent Bonds for the Holding Activation and Release of Mitochondrial Enzymes, 240
Rappay, Dr Gy Blocking the Ninhydrin-Schiff Reaction with Copper Ions, 274
Rask-Nielsen, Dr R Evidence of Murine, Virus-induced Paraprotein-producing Leukæmia and its Relation to Other Virus-induced Leukæmias, 440
Rastas, J , et *al* Transport of Ions Across Membranes, 1069
Rastogi, R G Lunar Tides in the Equatorial Electrojet and in the Ionosphere over the Magnetic Equator, 1083
Rat Heart Muscle by Fatty Acids, Ketone Bodies, Pyruvate, Diabetes and Starvation Citrate as an Intermediary in the Inhibition of Phosphofructokinase in (P B Garland et *al*), 169
Rat Liver Mitochondria Effect of Vitamin B_6 and its Analogues on the Swelling of (Dr P R Pal), 173
Rat Liver Tumours induced by Feeding 4-Dimethylaminoazobenzene Serum Optical Rotation during the Development of (G Fare), 481
Rat Muscles measured in Plasma Resting Potential of Isolated (Dr R P Kernan), 474
Ratcliffe, J A Geophysics The Earth's Environment—Lectures delivered at Les Houches, 1962, *review*, 1
  Physique Solaire et Géophysique, *review*, 1
Rate of Equilibration of the Contents of the Gut of *Anopheles quadrimaculatus* Larvæ with the Surrounding Medium (Dr S Friedman), 605
Rathbone, L , and Maroney, P M Preparation of Phosphatidylserine, 887
Rats Effect of Posterior Pituitary Extracts on the Life-span of Old (Prof S M Friedman and Prof C L Friedman), 237
  Influence of Lactation on the Retention of a Single Dose of Strontium-90 in (Dr W E Kollmer and Dr H Kriegel), 187
Rats with Arteriosclerosis Abnormal Glucose Tolerance in Repeatedly Bred (Prof B C Wexler and Dr C T Fischer), 133
Ratzenhofer, Prof M , and Zangger, J Drastic Morphological Change without Loss of Viability in Ehrlich Ascites Tumour Cells after Incubation with Strongly Diluted Formaldehyde, 184
Raudsepp, Eugene Managing Creative Scientists and Engineers, *review* by R Brightman, 1032

Rawson, D S , and Bell, Dr J D Geology of the East Rutts (South Devon), 770
Ray, A B , and Biswas, A K Surface-active Characteristics of Sodium Salts of Anacardic Acids of Varying Unsaturation, 1203
Raymont, Prof John E G Plankton and Productivity in the Oceans, *review* by Dr D Cushing, 975
Rea, Dr D G Evidence for Life on Mars, 114
Reaction Kinetics of the Atomic Oxygen-Graphite System (C E Gleit, W D Holland and R C Wrigley), 69
Read, Prof H H Awarded The Royal Society Royal Medal, 1963, 734, 1255
Read, V H , et *al* Uptake of Tritiated Aldosterone by Rat Tissues, 788
Reardon, W D , et *al* Rejuvenation of Gas Liquid Chromatography Columns *in situ*, 467
Recent Advances in Allergy Research (edited by F Hahn, P Kallos and G B West), *review* by Dr N G Waton, 1038
Recent Soviet Contributions to Mathematics (edited by Dr J P LaSalle and Dr S Lefschetz), *review* by Prof T A A Broadbent, 986
Reciprocal Effects of Insect and Plant-growth Substances (Dr D B Carlisle, D J Osborne, P E Ellis and J E Moorhouse), 1230
Reckitt and Sons, Ltd , New Biological Research Laboratories (G Colman Green), 529
Records of the Australian Museum, 25, No 13, 1962, 1051
Recovery Effects of Homologous Testes DNA Injected into Total-Body Irradiated (600R) Infantile Rats and Mice (Miss N Savković), 1073
Recrystallization and Grain Boundary Sliding in a Magnesium Alloy (J E Harris), 1197
Red Avadavat and its Development in Other Birds Significance of Allopreening in the (J H Sparks), 281
Red Blood Cells for Glutathione Synthesis Utilization of Alpha-Ketoglutarate by (Dr M D Sass), 1209
Red Cell, Human, Phosphogluconate Dehydrogenases (R A Fildes and C W Parr), 890
Red Cells Cross-relations of *Escherichia* and Human (Miss B J Ten Raa and Dr C R Macpherson), 182
Red Eye Colour Mutation in *Culex pipiens* after X-irradiation (A Wild), 917
Red Grouse Isolation of Louping ill Virus from the (Dr H Williams et *al*), 193
Redmond, W J , et *al* Molybdenum and Iron Requirements for Nitrate Reductase in *Photobacterium sepia*, 1125
Reduction of Radiation Mortality through Magnetic Pre-treatment (Prof M F Barnothy), 279
Rees, Dr C W Appointed reader in Organic Chemistry, 317
Rees, D B , et *al* Ionization Coefficients in Helium at High Pressures, 58
Reeve, T S , et *al* Effect of Nitrogen Mustard on Erythrocyte Acetylcholinesterase, 1110
Refractive Index and Concentration of Solutions Relationship between (F A Glover and J D S Goulden), 1165
Rege, Mrs V P , et *al* Three New Trisaccharides obtained from Human Blood-Group A, B, H and Le^a Substances Possible Sugar Sequences in the Carbohydrate Chains, 532
Register of Research in the Human Sciences (1960-63), compiled by the Warren Spring Laboratory, second edition, 835
Regoli, Dr D , and Clark, V Prevention by Adenosine of the Effect of Adenosine Diphosphate on the Concentration of Circulating Platelets, 546
Reid, Dr R L Appointed associate director of the Hill Farming Research Organization, 523
Reif, Prof A E , and Allen, Dr J M V Specificity of Isoantisera against Leukæmic and Thymic Lymphocytes, 1332
Reinert, Prof J Growth of Single Cells from Higher Plants on Synthetic Media, 90
Reite, O B , et *al* Development of Bradycardia during Submersion of the Duck, 684
Rejuvenation of Gas Liquid Chromatography Columns *in situ* (D S Payn, W D Reardon and L J Harvey), 467
Relation between the Length of Exposure to Alkali and Yield of Ribonucleic Acid from Plant-leaf Tissue (Prof D F Millikan and E E Pickett), 470
Relation of Body-weight to Hepatic Glutamic Pyruvic Transaminase Activity (Prof C E Cornelius), 580
Relationship between Consistency of Wheat Grain and Flour Diastatic Activity (P C Williams), 172
Relationship between Refractive Index and Concentration of Solutions (F A Glover and J D S Goulden), 1165
Relationship between Venous Pressure and Cortical Blood Flow (I Jacobson, A M Harper and D G McDowall) 173
Relationship of Antigenicity and Degree of Tolerance to Heterologous Serum Albumins in *C57BL/6* Mice (Dr F M Dietrich), 483
Relationship of Relative Leaf Growth Rate to Net Assimilation Rate and its Relevance to the Physiological Analysis of Plant Yield (J E Jackson), 909
Relative Biological Efficiency of Negative μ-Mesons and Cobalt-60 γ-Rays (Dr D R Davies, A H Sparrow, R G Woodley and A Maschke), 277
Relative Retention in Immediate Memory Determined by the Missing Scan Method (Dr H Buschke), 1129
Renfrow, W B , and Hawkins, P J Organic Chemistry Laboratory Operations, *review* by D C Firth, 724
Renshaw Cells Integration at an Inhibitory Interneurone Inhibition of (Prof V J Wilson and Dr W H Talbot), 1325
Rensselaer Polytechnic Institute Appointments, 118
Reproduction in a Free-living Population of Domestic Rabbits, *Oryctolagus cuniculus* (L), on a Sub-Antarctic Island (E Shipp, K Keith, R L Hughes and K Myers), 858
Reptile and Amphibian Lung Lining in Bird, (R E Pattle and D A W Hopkinson), 894
Research and Design in Engineering (H Clausen), 1152
Research in Education, 505
Research in Textiles, Colour Chemistry and Dyeing, 531
Research, Innovation and Economic Growth (substance of a paper given at the British Association for the Advancement of Science, Meeting, 1963, by K Pavitt), 206
Research Professorship, title given to Dame Honor Fell, 631
Reserpine Sexual Changes in the Male Rat following Chronic Administration of (R Fuller), 585
Reserpine Anatagonism in Mice Elevation by Propynylamines of Rat Tissue Norepinephrine-levels and (Dr J R McLean and Dr G Chen), 686
Reserpinized Rats Effects of α-Methyl DOPA and DOPA on the Amphetamine Excitatory Response in (R M Quinton and G Halliwell), 178
Residue Reviews, Vols 1–3 (edited by Francis A Gunther), *review* by J T Martin, 971
Resins Hydrolysis of some Antibiotics and of their Decomposition Products in the Presence of Cation Exchange (Prof M G Brazhnikova and M K Kudinova), 167
Resistance of Phytohæmagglutinin-treated Lymphocytes to X-rays and Nitrogen Mustard (Dr R Schrek and Dr S Stefani), 482
Resistance to Bacterial Blight of Cotton in Albar (N L Innes), 387
Resistance to Finger Cooling Related to Physical Fitness (Dr C J Eagan), 851
Resolution of some Problems Concerning the Reduced Diphosphopyridine Nucleotide Dehydrogenase of the Respiratory Chain (Dr T Cremona and Dr E B Kearney), 542
Resorption of Necrotic Lens Material by a Newly Formed Lens Capsule in Certain Types of Cataract (Dr A Brini, A Porte and M E Stoeckel), 796
Resources of Petroleum How Much Oil ? (H B Milner), 223
Respiratory Chain Resolution of some Problems Concerning the Reduced Diphosphopyridine Nucleotide Dehydrogenase of the (Dr T Cremona and Dr E B Kearney), 542
Response to Mice to a Chromic Phosphate Injection (H P Gump), 475
Responses of Germ-free Mice to Friend Virus (Prof E A Mirand and J T Grace jun), 92
Resting Potential of Isolated Rat Muscles measured in Plasma (Dr R P Kernan) 474
Reticulo-endothelial System Radiation Protection Effect and Pharmacologically Changed Activity of the (Dr K Flemming), 1117
Retina Analysis of *A* and *B* Wave Interaction in the Rabbit (Dr E L Pautler and Dr R A Wilson), 1212

Retinas Visual Pigments in Human and Monkey (P K Brown and Prof G Wald), 37
Return of the Nene to Hawaii, 945
Re-utilization of Deoxyribonucleic Acid from Cells other than Leucocytes (Prof K E Fichtelius and O Groth), 587
Reversal Effect with Pauses on Mixed Schedules of Reinforcement (Prof J D Keehn), 1124

University Grants in Great Britain, 527
University—Potential Scientific Manpower, 1265
University of Aberdeen Appointments, 837
University of Adelaide Waite chair of agricultural biochemistry, 406
University of Birmingham Appointments, 21, 317, 522, 941
University of Bristol Appointments, 837
University of California Appointments, 314
University of Cambridge Department of Applied Economics—British Association for Commerce and Industrial Education, 633
  Dunn Nutritional Laboratory, director appointed, 632
University of East Anglia Appointments, 837, 1151
University of Glasgow Appointments, 118
University of Keele Statistical Research Unit in Sociology, 1050
University of Lancaster Appointments, 522
University of Leeds Appointments, 938
  Nuffield chair of Psychiatry, 405
University of Leicester Prof R H Pritchard appointed to the chair of Genetics, 834
University of Liverpool Nuffield Unit of Medical Genetics, 735
University of London Appointments, 317, 522, 1052, 1264
  The *Calendar* 1963-64, 409
  Substance of Sir John Lockwood's inaugural address at the opening session of the School of Pharmacy, 511
  Substance of Lord Robbins' address as Special Visitor to the Imperial College of Science and Technology, 621
University of Malaya Appointments, 1049
University of Melbourne Substance of the first David Rivett Memorial Lecture, 397, 405
University of Oxford Appointments, 215
  Diploma in Soil Science, 524
University of St Andrews Appointments, 941
University of Sheffield Appointments, 409, 632
University of Southampton Appointments, 938
  Substance of Sir Willis Jackson's Fawley Lecture, 1145
University of Warwick Appointments, 522, 734
University of York Appointments, 314
Unsaturation Molecular Formula and Degree of (D A Laws), 1202
Unseen World, The (Prof René Dubos), *review* by Prof R Barer, 984
Upadhya, M D , and Swaminathan, Dr M S Deoxyribonucleic Acid and the Ancestry of Wheat, 713
Upham, H C , and Haley, Prof T J Skin Reaction to Intradermal Injection of Rare Earths, 271
Uptake of Particulate Matter within the Thymus of Adult and New-born Mice (Dr I Green and K Bloch), 1099
Uranium Quantitative Electrodeposition of Thorium and (W Parker *et al*), 457
Uranium-Lead Ages due to Continuous Loss of Lead Discordant (Prof T J Ulrych), 561
Uranium Monophosphide Vaporization of (Prof K A Gingerich et *al*), 774
Uranyl Ion Experimental Evidence for the Triplet Character of the Lowest Excited State of the (Miss M M Fayt et *al*), 355
Uranyl Nitrate Ketone Solutions Formation of Peroxidic Precipitate in the Radiolysis of (J Teply and V Stulik), 671
Urbaschek, Dr B , et *al* Immunological Changes and Therapeutic Effects o Convalescent Serum after Injury by Burns, 273
Urea with Jute on the Photochemical Degradation of the Fibre Effect of Reaction of (Dr H P Bhattacherjee et *al*), 882
Urethan (Ethyl Carbamate) of Virus Induction of Leukæmia in *C3H* Mice Inhibition by (Dr L W Law and A Precerutti), 692
Uri, Dr J , et *al* Production of 6-Aminopenicillanic Acid by Dermatophytes, 896
Urinary Adrenocortical Steroids 'Sephadex' Gel Filtration as a Method of Purification of (D Gupta), 574
Urinary Isovalthine Configuration of (S Ohmori et *al*), 678
Urinary Steroid Hormones Medieval Preparations of (Dr Lu Gwei-Djen and Dr J Needham), 1047
Urine Excretion of Neostigmine labelled with Carbon-14 in (J B Roberts et *al*), 1330
Urine Phenylalanine in Phenylketonuric Screening Direct Microbiological Assay for (C Scheel and H K Berry), 70
Urodele Limbs Wounds and the Polarity of Implant-induced Accessory (Dr L N Ruben and Jean Stevens), 797
Ursell, H D Centenary of the Birth of W H Young, F R S , 1274
Use of a Combined Complement-fixing Antigen to Detect Arthropod-borne Viral Infection (D E Carey), 1024
Use of a Digital Computer for Evaluating Ultracentrifuge Data (S P Spragg), 1200
Use of an Electron Beam for detecting Superconducting Domains of Lead in its Intermediate State (Prof M Blackman, A E Curzon and A T Pawlowicz), 157
Use of Ion Exchange Resins to Alter the Concentrations of Individual Inorganic Ions in Blood *in vivo* (Dr M A Kumar and I McIntyre), 181
Use of Polymethyl Methacrylate in preparing Thin Sections of Recent Sediments (J R Moore III and S H Garraway), 62
Use of Synergy in the Identification of Strains of Citrus Yellow Vein Virus (Dr L G Weathers), 812
Use of Xenon and Krypton as Carrier Gases for a Highly Sensitive Detection System for Gas Chromatography (Prof S R Lipsky and M M Shahin), 566
Ustilago nuda (Jens) Rostr Seedling Inoculation with (T Kavanagh), 1021
Uterus Electrical Activity of the Parturient Human (Dr A I Csapo and Dr H Takeda), 680
Utilization of Alpha-Ketoglutarate by Red Blood Cells for Glutathione Synthesis (Dr M D Sass), 1209

VACCINES with Incorporated Adjuvants Protective Effect of Killed Trypanosome (P Johnson et *al*), 83
Vaccinial Preparations Treatment of Canine Neoplasms with Autogenous (Dr C W Riggs), 233
Vacuum Sublimation Epitaxial Growth of Silicon by (Y Nannichi), 1087
Vagus Nerve Anorexia produced by Direct-current Blockade of the (J H Penaloza-Rojas and Dr M Russek), 176
Valentine, Miss G , et *al* Conversion of DPNH Dehydrogenase to DPNH-cytochrome Reductase by Thiourea, 673
Valu, G , et *al* Production of 6-Aminopenicillanic Acid by Dermatophytes, 896
Vandeput, Miss E M , et *al* Experimental Evidence for the Triplet Character of the Lowest Excited State of the Uranyl Ion, 355
Vanderhaeghe, H , et *al* Identification of *p*-Hydroxyphenoxymethyl Penicillin as a Metabolite of Phenoxymethyl Penicillin, 891
Van Duuren, Prof B L , et *al* Tumour-enhancing Activity of the Active Principles of *Croton tiglium* L , 1115

WATSON

PHOTOMICRO CAMERA with Polaroid® Land Back

Just as the introduction of the Polaroid Land system of virtually instantaneous prints opened up a new era in orthodox photography, so the application of this same system to photomicrography offers vast new possibilities and great advantages to the microscopist

The essential part of the Polaroid Land apparatus, the camera back, has been adapted to fit the basic unit of the Watson Eyepiece Camera so that examination of positive photomicrographs is possible within seconds of exposure The camera is rigidly supported above a levelling base which is large enough to accommodate a wide range of microscopes

The almost instant availability of a print means that the photomicrograph can be attached *at once* to the written report of visual observation Moreover, should there be something amiss with contrast or focus, the fault can be picked up immediately, necessary corrections made, and a new exposure taken This is particularly important where the phenomena under examination are of a transitory nature

And with the introduction of ultra high-speed PolaScope film, rated at 10,000 ASA, photomicrography is now a perfectly feasible proposition under lighting conditions which hitherto would have been considered impossible

The Watson Photomicro Camera with Polaroid Land Back produces direct paper positive prints size $3\frac{1}{4}'' \times 4\frac{1}{4}''$, or black and white transparencies for projection.

'Polaroid' & 'PolaScope' reg trade marks of Polaroid Corp

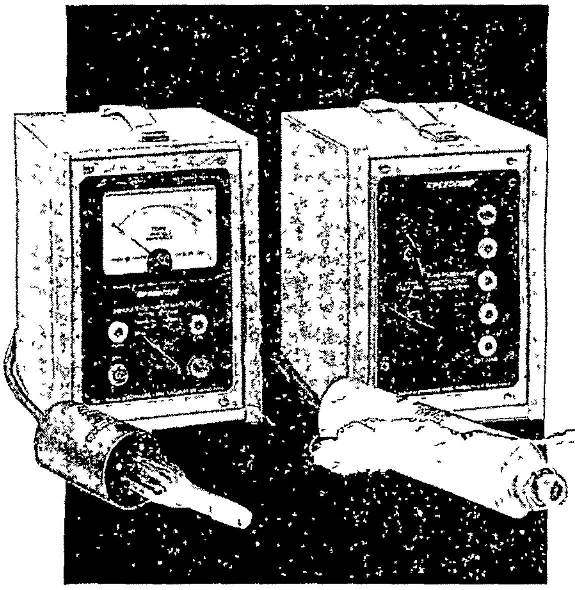
PIRANI MODEL 8 INDICATING & RECORDING GAUGES

These new "SPEEDIVAC" Pirani gauges are of the constant voltage bridge type The bridge voltage is transistor stabilised and, therefore, independent of load variations resulting from pressure changes at the gauge head, and virtually independent of mains supply fluctuations up to 15% This high stability, and the elimination of manual bridge voltage adjustment makes the Series 8 ideally suitable for use with a recorder. With the multi-head switch unit up to six gauge heads can be connected for indication and recording.

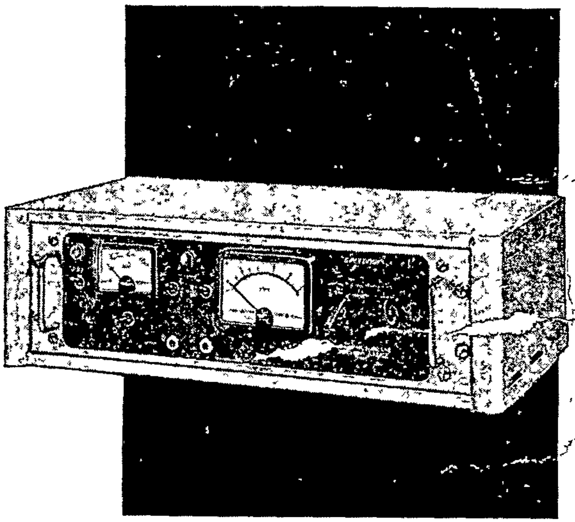


10 torr to 10^{-3} torr in two ranges (Model 8-1)
1 torr to 10^{-4} torr in two ranges (Model 8-2)

NEW
"SPEEDIVAC"
HIGH
VACUUM
GAUGES

IONISATION-PIRANI GAUGE MODEL 1

To match the higher vacuum performances of the latest "SPEEDIVAC" equipment we have developed a combined thermionic and Pirani gauge control unit which indicates pressures between 1 torr and 10^{-8} torr. The tremendous advantage of this single, compact unit (cabinet size 19 x 5½ in.) (492 x 140 mm.) is that one ionisation gauge head and two Pirani heads can be connected for simultaneous indication of both fine and backing side pressures.



1 torr to 10^{-8} torr

Another new "SPEEDIVAC" product for 1963

"Speedivac" products and service are available internationally

SCIENTIFIC PYE INSTRUMENTS

From the world's most accurate pH meter to an incomparably rugged flame-proof industrial pH amplifier, from an unequalled range of pH electrodes to entirely comprehensive process control systems—Pye approach every aspect of pH measurement with massive know-how—give you Pye Precision every time

Ten different Pye pH meters and more than 200 different Pye Ingold pH electrodes permit a perfect measuring system to be tailored for any application Pye engineers and chemists with extensive laboratory facilities for chemical analysis and process simulation will examine any problem involving pH. They can recommend the most suitable laboratory equipment and can design and install, or commission, complete systems for industrial pH monitoring and control To ensure optimum performance over the years, Pye provide regular contractual maintenance in the U.K. and Pye Agents provide similar facilities in many parts of the world A short-form catalogue, application sheets and technical data can be sent to you today.

THE PRICE OF GROWTH*

PHYSICS LI [illegible] RY

THE growth of output is now receiving more emphasis than ever before This is so in the rich countries as well as in the poor, it is true of the Communist world even more than of the West Paradoxically the affluent society has been much criticized in the West Growth and affluence are both emotive words, one good and the other bad

There are several reasons for the increased emphasis on growth Competition has been stimulated by international league tables prepared by economic statisticians, who may be the most subfusc of agitators, but are not the least powerful The needs of national security afford another reason Another is the reluctant but growing recognition that little can be achieved by the redistribution of income, the new emphasis therefore reflects a new realism which may imply a less apocalyptic view of social improvement Moreover, the high degree of success in preventing unemployment since the War has diverted attention to the importance of raising productivity

Growth often involves a price. How much should be sacrificed in other directions for the sake of how much more growth? A more rapid growth of output must not be described as an economic objective while personal freedom or defence or the preservation of local communities are held to be non-economic objectives This is a misuse of terms Economics deals with means not ends Formal welfare analysis has been cautious but modern applied economics is less so It must be recognized that genuine conflicts involving value judgements will be encountered If they do nothing else, economists can at least help to disentangle the issues, and to indicate where possible the orders of magnitude, and to point out where the ultimate value judgements must be made

It has been held that growth would be fostered if the Trade Unions were to be emasculated, as they have been in the U S S R But we would hesitate in the West before overthrowing one of the most effective forms of countervailing power confronting the State Of course, the factual assumptions need to be examined in detail and the possibility of a third alternative investigated. But sacrifices may sometimes have to be accepted Cost-inflation, 'stop - start' and a slower rate of growth may result from a refusal to enforce an incomes policy if such a policy is not accepted voluntarily This should be borne in mind in making international comparisons

If growth were to be given the emphasis in Great Britain which it receives in Communist countries, the best managers might not be greatly affected but the weaker managers would be and the inquisitions and the punishments which would accompany such a policy would represent, in a broader sense, a loss of social efficiency Another question is how far equality should be sacrificed for the sake of growth Even if rapid growth does not mean that there are losers as well as gainers, the gap between rich and poor may sometimes widen domestically or internationally Would more equality be preferred even if everyone were poor? Regional policy affords another example rapid growth is not consistent with bolstering up industry in every location whether suitable or otherwise

The needs of growth will often conflict with other needs, but these conflicts must not be exaggerated Rapid growth will often be the best way of solving other problems as well as raising the average level of income For example, growth in the West has clearly drawn much of the sting from inequality, or again, within the less-prosperous areas. there may be potential zones of growth and the national objective of higher output may coincide with local needs Sometimes an apparent conflict reflects a failure to appreciate the facts It would be foolish to direct labour into particular occupations merely for the sake of growth, direction is inefficient, and individual freedom would often be sacrificed for no purpose Moreover, the quantities must be examined Thus the fashionable claim that for the sake of growth Britain must spend less abroad on aid and defence ignores the orders of magnitude and implies a disproportionate sacrifice for a modest gain

Finally, the role of the economist in these matters was reviewed by Prof Wilson He showed how the economist can break up complex propositions into their consistent parts measurable factual considerations, non-measurable factual considerations; considerations of a kind not professionally studied by economists such as public health or strategy, ultimate value judgements. The value judgements will often be present, but it is suggested that they will give rise to less disagreement than is frequently supposed provided the rest of the analysis has been adequately performed

THE SUN AND THE EARTH'S ENVIRONMENT

Geophysics

The Earth's Environment—Lectures delivered at Les Houches during the 1962 Session of the Summer School of Theoretical Physics, University of Grenoble. Edited by C DeWitt, J. Hieblot and A. Lebeau. Pp xiv + 624 (New York and London. Gordon and Breach, 1963) 10 50 dollars, cloth, 8 50 dollars, paper.

Physique Solaire et Géophysique

Par Prof A Dauvillier. Pp 362 + 1 planche (Paris. Masson et Cie, 1962) 72 NF

DURING the past few years there has been intensive study of the Earth's upper atmosphere and of that part of the Sun's outer envelope which lies beyond it The fascination of this field of research, and the availability of new facts resulting from experiments in rockets and satellites, have led to a voluminous outpouring of publications, some important and some trivial The writings are so numerous that even those closely interested in the subject find it difficult to follow the advance of their own little speciality, those studying the subject for the first time find it unusually confusing Any writings which aim at summarizing the results either for the expert or for those starting research on the subject are particularly welcome, and deserve close examination to decide just how useful they are

Geophysics The Earth's Environment contains chapters based on a series of lectures delivered at Les Houches during the 1962 session of the summer school of theoretical physics, the University of Grenoble

The subjects and authors are as follows "Introduction à l'Electrodynamique des Plasmas" (J F Denisse), "Lectures on Magnetoionic Theory" (K G Budden), "Motion of Charged Particles in Earth's Magnetic Field" (J W Chamberlain) "La Diffusion des Ondes Electromagnétiques par les Plasmas" (R Benoit), "La Constitution et la Composition de l'Atmosphère Supérieure" (Marcel Nicolet), "The Structure of the Ionosphere" (G J F MacDonald), "Introduction à l'étude de la Luminescence Atmosphérique et de l'aurore Polaire" (D Barbier), "Solar Plasma, Geomagnetism and Aurora" (Sydney Chapman), "The Structure of the Exosphere or Adventures in Velocity Space" (J W Dungey), "Whistlers" (R Gallet), "Motions in the High Atmosphere" (G. J. F MacDonald)

The first part of the book, devoted to basic theory, will perhaps prove the most useful to many readers, since it collects, in an admirably succinct way, the important theoretical considerations from a wide field of knowledge Denisse deals with such topics as the diamagnetism of a plasma, the diffusion of magnetic field into a plasma, Alfvén waves, magneto-sound waves, Landau damping. Budden discusses, among other topics, the travel of wave-packets and the concept of rays, the ionospheric dispersion of pulses and short wave-trains, the concept of wave admittance applied to the reflexion of waves from the ionosphere, and the phase-integral method of calculation Chamberlain's treatment of the orbits of magnetically trapped particles, in which he shows the relation between the approaches of Stormer, Alfvén, and the hydromagnetic theory, is particularly helpful Dungey's article might well have been included in Part 1, it contains a useful section on hydromagnetic waves

From Part 2, dealing with the composition and constitution of the Earth's environment, it is natural to pick out the articles by Nicolet and Chapman for particular comment Among other topics, Nicolet deals with the constitution and temperature of the neutral atmosphere, the effect on it of solar radiation, and the diffusion of the resulting ions and electrons Chapman discusses geomagnetism, the solar plasma on its way to the Earth, the mutual influence of the solar gas and the geomagnetic field, magnetic disturbance and aurora, and the ring current and its effects Both these chapters take the form of concise summarized progress reports from workers active in their own fields They are most valuable

The foregoing list of authors and subjects guarantees the scholarly nature and the reliability of the treatment, what it does not indicate is the admirably concise and clear way in which the articles are written A considerable effort has clearly been put into the selection of the material and its presentation in a straightforward and logical manner The highly successful outcome results probably from the fact that these were lectures in which emphasis had to be placed on essentials and fundamentals The authors have suceeded in dealing with the more important and newer parts of their subjects without becoming involved in detail, or losing touch with fundamental principles

The book is up to date, authoritative, selective, and unusually well composed It will be an essential part of the library of all serious workers concerned with the Earth's environment Beginners will find in it a succinct introduction to their chosen subject of research and to related fields

Physique Solaire et Géophysique, by A Dauvillier, might be expected, from its title, to be equally valuable Surprisingly, however, it contains little dealing with research work of recent years, and seems to be largely an account of the subject as known in about 1950 The sub-title lists the contents of the book "L'Héliomagnetisme—le vent solaire l'émission d'électrons solaires rélativistes, la théorie oscillatoire de l'activité solaire, rélations entre les phenomènes solaires et terrestres" The portions on solar-terrestrial relations are so inadequate that the inclusion of *Géophysique* in the title is misleading For example, the section on "Geomagnetism, Variations and Origin" lists 46 references all dated prior to 1952, and occupies only 16 pages, that on the ionosphere lists 23 references previous to 1952 and 6 after that date and occupies 8 pages

The book from Les Houches is so outstandingly good that it is perhaps a little unfair to review the other with it, but even if it had been considered alone, the book *Physique Solaire et Géophysique* could scarcely be described as an up-to-date text-book for any purpose

J A RATCLIFFE

MASS TRANSFER SIMPLIFIED

Convective Mass Transfer

An Introduction. By Prof D B Spalding Pp xv + 448 (London Edward Arnold (Publishers), Ltd, 1963) 70*s* net

PROF SPALDING is known for his idiosyncratic approach to heat and mass transfer This introductory volume sees his method displayed to full advantage and may well win converts to his cause His enthusiasm and determination are obviously inexhaustible, for there is not a sloppy paragraph in the whole book

After a model preface which explains his present purpose, he surveys the field of his endeavour in a short introductory chapter, this gracefully encompasses such diverse topics as evaporation from the ocean, the formation of smoke in a flame, the ablation of a meteorite and the Bessemer converter, besides the many separation and extraction processes of chemical engineering With admirable precision, he then enunciates his "Provisional Theory of Mass Transfer" (some might prefer the word interpretation to the word theory, but this is to be petty), and describes the two concepts on which it is based Reynolds flow and driving force By choosing a graded sequence of real phenomena, the author shows how these 'fundamental' quantities are derived in progressively more complex examples of mass and heat transfer across an interface, and finally shows how transfer rates can be calculated in a comprehensive range of practical circumstances, most of them in the field of chemical engineering and fuel technology

Simplicity and directness, ever desirable qualities in an engineer, are the mainspring of his approach An engineer seeks to calculate mass-transfer rates, not necessarily to understand the physical and chemical processes leading to them Prof Spalding evidently realizes this, and has made a great effort in this volume to provide a consistent and comprehensive elementary text-book for the practising engineer It proves equally suited to undergraduate teaching This utilitarian attitude is not the present trend in pedagogy, and for this reason such a book deserves careful consideration The author succeeds magnificently in his task of providing a simple framework that will admit the results of modern theory and experiment through progressive elaboration of the description of the 'fundamental' quantities Constants become functions, new dimensionless groups appear, boundary conditions are refined

All this is done without reference to anything more elaborate than derivatives and integrals The results of more exact theories relying on the solution of differential equations are quoted and used, but their derivation is relegated to later volumes This 'layman's' approach uses engineering science as a means to an end, and no more A refreshing verdict and one that should commend itself to those who are attempting to foster technological progress in Britain As the numbers undergoing higher education increase, teachers will need more and more text-books of this type, in which the complicated results of modern science are digested, formalized, simplified and shown to be useful in well-defined contexts Intending authors could do little better than study Prof Spalding's exemplary model Starting from a wealth of scholarship and experience, he has provided a lucid and logically developed exposition of a topic that can now almost be regarded as a discipline in its own right A generous number of worked examples and a profusion of diagrams further enhance the value of this work, which is singularly free from the errors, omissions, ambiguities and inelegancies that characterize most text-books published to-day

J R. A Pearson

PETROLOGICAL MINERALOGY

Rock-forming Minerals

By Prof W A Deer, Dr R A Howie and Dr J Zussman Vol 2 Chain Silicates Pp x+379 Vol 3 Sheet Silicates Pp x+270 Vol 4 Framework Silicates Pp x+435 Vol 5 Non-Silicates Pp ix+371 (London Longmans, Green and Co , Ltd , 1962–63.) 95*s* each volume

THE first volume of this series was reviewed in *Nature* of July 7, 1962, p 4 The work is now complete in four further volumes of similar average length of about 350 pages Variations of chemical composition within a group, discussed on a structural basis, are treated throughout as fully as in Volume 1 The descriptions of the pyroxene group and of the amphibole group, for example, each occupy a little less than one-half of volume 2, and each account is accompanied by more than 200 selected analyses (there are more than 1,600 in the whole work), with optical data where available and the appropriate structural recalculations of numbers of ions The account of each species concludes with a valuable discussion of the paragenesis

It is difficult to find fault with the selections of references to recent work appended to the accounts of each species References are stated to be comprehensive to 1959 (in Volume 4 to 1960), but there are many later additions—from Volume 4 one can trace stishovite, and recent work on melanophlogite, through references dated 1962 References are also given to selected classical papers, and here one sometimes misses a favourite, there seems to be no reference, for example, to Wahl's work on pyroxenes A similar problem of selection has faced the authors in the matter of obsolescent mineral names In Volume 2 there are indexed references to names such as magnophorite, osannite, and imerinite, though they are discarded as unnecessary, one cannot, however, trace damourite, gilbertite, or margarodite through Volume 3 Among preferred spellings are piemontite, katophorite, and felspar

I have noticed even fewer printer's errors in these volumes than in Volume 1 This strengthens confidence in the accuracy of reproduction of the whole mass of numerical data, which can, of course, only be checked in detail by use The index 110 is misplaced in Fig 24 *b* of Volume 4, and the indexing of the figure of barytes is not in accordance with the structural description It is not clear what is implied by the assertion, in the tabular statement of properties, that the *orthorhombic* pyroxenes show 'simple and lamellar' twinning on {100}, though there is, of course, a discussion of the significance of the lamellar structures later in the text Fassaite is characterized, surely, by the strong development of the form {110}, and not of the zone [110] Structurally it is improbable that periclase shows an octahedral cleavage though the statement is repeated in many text-books

Inevitably, the speed with which mineralogical research is progressing means that some passages in these volumes already call for modification—the phase diagrams of Figs 15 and 17 of Volume 2, for example, in the light of work published since 1960 One hopes that the make-up in five reasonably sized volumes (which are a delight to handle) will enable the authors more easily to keep pace with the revised editions which will surely be demanded This sub-division will also enable individuals to avoid the expense of the whole series, variously described by reviewers of Volume 1 in terms ranging from "rather expensive" to "lamentable", by acquiring only the volumes with which they are directly concerned It seems likely that Volumes 2 and 4 will be most consulted, closely followed by Volume 1 Specialized literature already exists in the field of the clay-minerals and their allies, covered in the last third of Volume 3, and also for a number of the groups of non-silicates in Volume 5, such as the opaque ores In the remainder of the series, however, covering major mineral groups for which no comprehensive literature has hitherto been available, the authors have gone far beyond mere compilation and provide accounts which are informative and critical There is no general index to the five volumes, this is little drawback to tracing mineral descriptions in view of the clear-cut division of the first four volumes on the basis of structural types, but it does sometimes make it less easy to locate more general matter such as references to a particular system

Reviewing the work as a whole, one is left with a feeling of gratitude to the three authors for undertaking this very necessary but highly onerous task, and with nothing but admiration of the successful way in which they have carried it out Just as one has automatically turned to 'Dana' for crystallographic data, and to 'Winchell' for optical data over the whole field of minerals, so 'Deer, Howie, and Zussman' will certainly establish itself as the standard source of information on the chemical, structural, and optical properties of the important rock-forming minerals

F C Phillips

DIAMONDS IN INDUSTRY

Proceedings of the First International Congress on Diamonds in Industry

Held at the Centre des Conférences Internationales, Paris, 28 May–2 June, 1962 Pp xi+407 (London Industrial Diamond Information Bureau, 1963) n p

THIS handsome volume of 400 quarto pages provides a valuable permanent record of papers read and discussed at the first International Congress on Diamonds in Industry, which was opened in Paris on Monday, May 28, 1962, and closed on the following Saturday No fewer than 38 quite important papers were presented at the Congress, and in most cases were followed by a lively discussion The inclusion of a report of these discussions in the symposium adds considerably not only to its scientific and technological but also to its human interest

Diamond is, of course, of outstanding importance as a gemstone and (because of its extreme hardness) as an industrial material, but it is also of very special interest in solid-state physics on account of its unique behaviour and the (largely unpredictable) variations in its behaviour Although its elementary composition has been realized for centuries and its crystal structure was one of the first (1913) to be established by the methods of X-ray crystal analysis, this was far from meaning that our knowledge of the mineral was complete The discovery that, based on differences in their absorptive properties, diamonds can be classified into two 'types' was described by Robertson, Fox and Martin (1931) in a famous paper and served as a signal for further research In succeeding decades the interrelation of absorption and fluorescence, the alterations brought about by various forms of irradiation, the 'counting' and semi-conductive properties of certain specimens, and the first repeatable and large-scale production of diamond by artificial means, have all acted as further stimuli for investigation There is now scarcely any aspect of diamond behaviour which has not been closely studied by physicists, and the pace shows no signs of slackening

In recent years, credit for encouraging such intense activity in this field must be given to the de Beers group of diamond companies, which has not only established three well-equipped and well-staffed diamond laboratories in South Africa, but has also sponsored fundamental research in several universities in Britain, and provided specimens for research in all parts of the world Annual conferences have also been arranged at Oxford, Reading, Bristol, etc , where workers on diamond have given research reports and exchanged views

Although the Paris Congress was the first to be held on the industrial diamond, it had much in common with the previous discussions on diamond in general—particularly in the last 15 papers, which are grouped under the heading "Scientific Session" In fact it is symptomatic of modern trends in industry that only some half-dozen papers even in the "Technological Session" could be remotely understood by the non-scientist Sir Gordon Sutherland acted as general chairman of the technological session, and Prof Jean Wiart of the scientific session

The technological papers for the most part follow expected lines, as suggested by some of the titles, for example, "Determination of the Shape of Diamond Grit Particles"; "A Comparison of Different Methods of Particle Size Analysis", "Evaluation of Diamond Grit in Resin Bonded Diamond Wheels", "Theory of Grinding", etc

The purely scientific papers opened with a review of the semiconductivity of diamonds by Prof E W J Mitchell and of optical properties of electron- and neutron-irradiated diamond by Dr C D Clark, both of the University of Reading, where so much of the original work on these topics was carried out The Clarendon Laboratory, Oxford, another important centre for diamond research, was represented by Dr Eileen M Wilks on the hardness of diamond and by Dr R Berman on the graphite-diamond equilibrium diagram

From the Cavendish Laboratory, Cambridge, came a valuable contribution on fracture propagation in diamond, in which the main 'fracture' considered was the octahedral cleavage By means of high-speed photography, a maximum velocity of 7,200 metres per second was recorded for this cleavage Marked differences between the cleavage surfaces of Type I and Type II diamonds have been observed

No diamond conference would be complete without a contribution from Prof Tolansky, whose applications of multiple-beam interferometry have so enriched our knowledge of the detailed nature of diamond surfaces Tolansky gave an account of the surface topography of natural and synthetic diamonds, including crystals made by the General Electric Co of America, the de Beers laboratories, and the Allmanna Svenska Elektriska Aktiebolaget· notable differences were observed between crystals produced in each of these centres, and between all synthetic crystals and those found in Nature

An unusual contribution was one from Michael Seal (New Jersey) in which the experiments of Hannay and Moissan on the synthesis of diamond are re-examined Plastic replicas of the surfaces of the tiny fragments left by Hannay in the British Museum (Natural History) were prepared to enable them to be examined by electron microscopy and compared with the corresponding surfaces in natural and modern synthetic diamonds, and the experiments of Moissan were substantially repeated The residual fragments, after lengthy separation processes, had much in common with those described and figured by Moissan, and in some cases closely resembled diamond, though most were found to be silicon carbide or corundum Mr Seal kept a commendably open mind on the claims of these early pioneers

Space does not permit even the mention of many other valuable papers in this symposium Anyone interested in the properties of diamond will certainly wish to possess this volume The ample references at the end of each paper enable the reader to explore each subject in depth if required Mr Patrick Greene is to be congratulated on his success in assembling, editing, and where necessary translating this mass of information

MUTATION AND GENETICS

Mutation

An Introduction to Research on Mutagenesis By Dr. Charlotte Auerbach Part 1 Methods Pp xii+176+4 plates (Edinburgh and London Oliver and Boyd, Ltd , 1962) 12*s* 6*d* net

The Science of Genetics

By Dr Charlotte Auerbach (Hutchinson Science Library) Pp x+273 (London Hutchinson and Co (Publishers), Ltd , 1962) 21*s* net

DR CHARLOTTE AUERBACH has contributed two more books to the literature of genetics They are written with the economy and lucidity of style for which the author is already renowned, and each is admirably planned and executed for its purpose In *Mutation An Introduction to Research on Mutagenesis Part 1 Methods*, Auerbach introduces her subject with two short general chapters covering types of mutation, methods of distinguishing environmentally induced variations from truly genetic ones, mechanisms of mutation and the concept of mutation rate, and five basic rules for mutation research Methods and procedures for various organisms are then outlined under four main headings *Drosophila*, animals other than *Drosophila*, flowering plants and micro-organisms The last category occupies one-third of the book and includes explicit accounts of screening tests in *Neurospora* and bacteria, the detection of biochemical and other physiological mutations in fungi, algae and bacteria, and the genetical analysis of mutants in these types and in viruses A final chapter deals with new systems such as transforming principle and mammalian cells The book is illustrated by diagrams and tables which are helpful in supplementing the text and providing condensed material for reference Each group of chapters is followed by a few references to books and papers, with titles, and sometimes with a note about contents, making it easy for the reader to pursue particular topics This small book will be valuable not only to students and investigators in the field of mutation research. but also to many non-geneticists who need a means of understanding experiments in mutagenesis

The second book, *The Science of Genetics*, is an elementary text-book, taking the reader all the way from a definition of the subject to virus and bacterial genetics, transforming principle, and a description of the DNA double helix and its genetic code The stages in this journey are easy, the chapters are short and each follows smoothly from the one before, consolidating in unobtrusive but reassuring ways the progress already made No previous biological training is assumed The book is admirably suited for school use at the same time its range and substance are such as to make it rewarding also to the educated biologist, and few adult readers will fail to wish that an equally brief, lucid and informative text had been available in their younger days Here are all the fundamentals of the science, as well as a view into its more advanced chapters and its wider implications Mendel's laws, the chromosomal basis, linkage and crossing-over, sex-linked and lethal genes, quantitative characters, gene-controlled metabolic pathways, interaction between genes and environment, cytoplasmic inheritance, the genetic basis of evolution, eugenics, and much more

Illustrations are chosen primarily for their ability to make the point clear, but when possible from human genetics, or from familiar plants and animals. Throughout the book, the author's own sense of the fascination and excitement of her subject shows through the easy personal style of the writing Occasionally the reader is explicitly restrained from incorrectly extending genetical conclusions to human racial questions In this way the author shows her awareness of the readiness with which the human mind finds material to justify its prejudices.

More than eighty refreshingly informal drawings and diagrams by G. Auerbach Linker not only add charm and lightness to the book, but also play an essential part in supplementing the text There are a very short list of titles for further reading, and an index ALMA HOWARD

THE DAIRY COW

The Dairy Cow

Reproduction, Genetics, Nutrition, Habitat, Principal Diseases By C Craplet, translated by Catherine T M Herriott Pp xv+452. (London Edward Arnold (Publishers) Ltd, 1963) 130*s*

THIS volume consists of six parts, each dealing with one of the following subjects, reproduction and lactation, artificial insemination, genetics, nutrition, housing and disease The author is head of the Animal Husbandry Department in the Grignon School in France and the book was written first in French It would have been helpful if the author had supplied even a short foreword to explain his object in writing the book and to state clearly for whom he intended it, but he has not done so, and one cannot help wondering if the book originated as notes on which was based a series of lectures to students taking a general but fairly elementary course in animal husbandry, the notes in some parts applying, quite naturally, more to France than to Britain, and in some parts being now somewhat out of date

If, for example, one seeks information on iodinated protein, two page numbers are given in the index On p 258 the author explains that "unfortunately" experiments with iodinated protein are still in the laboratory stage, and yet on p 71 he states that the stimulating property of thyroxine on milk secretion "has been recommended to the breeder in the form of thyroxine or iodized protein administration" Neither statement is true for Britain, where work with iodinated protein reached the applied stage some 15 years ago or more, but where the use of thyroxine or iodinated protein is not recommended to breeders

On p 306, guidance is given on the seeding of pastures, but under the heading of "Density" (presumably amount of seed to use per acre) the author simply states, "see modern agricultural text-books" One might feel that in a book on the dairy cow, there would be little need to deal with reseeding of pastures since pasture management, like so many subjects to-day, is becoming more and more a matter for the expert, but if pasture management is to be discussed, surely the paragraph on density could have been a little more informative

Even the relative costs of barbed wire and electric fences are dealt with in this book on the dairy cow, but they are based on prices that prevailed, presumably in France, in 1948, fifteen years before the book was published, a period in which great changes in prices have occurred and in which the development of the electric fence has made much progress In calculating costs the wire fence taken by the author as an example consists of five strands of barbed wire, in Britain it is usually considered sufficient if the top strand only is barbed

Writing about the watering of cattle the author states, "In hot weather cows may drink 80 per cent more than usual, in cold weather their intake decreases slightly, so that heating the water is a good precaution to take" It is to be hoped that any British farmer who may see this statement will not feel that he must add the heating of drinking water for cows to his numerous duties unless the water happens to be undrinkable because it is frozen

In the section that deals with the utilization of the volatile fatty acids this curious sentence occurs, "Experimental work has revealed the facility with which tissues utilize acetic acid and this is the reason for the perfused heart of a rabbit using up more acetate per hour than glucose" But why is that *the reason* ?

In discussing eradication of mastitis on p 391, the author recommends disinfecting the udder with water sterilized with potassium chloride This would be quite ineffective; perhaps he means sodium hypochlorite Two pages later in dealing with staphylococcal mastitis the statement is made that "infected cows should be milked in the dry period for this will give excellent results"

Unfamiliar terms are used in discussing the chemical composition of milk, for example, "de-fatted dry extract" which presumably means solids-not-fat and "lime combined with casein", terms that must seem strange to a modern dairy chemist There are also some irritating little mistakes On p 246, for example, the phrase "permanent water" is used where a piped supply of water is meant, and nutrient supply is said to equal "nutritive value of food X quality consumed"—surely a mistake for "quantity consumed" In the index the name Voisin is given as Viosin Many workers are cited in the text but the book contains no list of references of any sort, so that the reader, unless he knows already, does not know where he can find the work cited or when it was done

This is all most disappointing, since the dairy cow is an important subject and the publishers of this English translation have certainly produced it in a most attractive form The whole lay-out, the type, the figures and the binding are of exceptionally high quality, so much so that a cursory glance might well suggest that the book ought to be well worth the money to a reader in Britain Alas, such a claim would be difficult to justify Indeed research and its application in veterinary and farm practice have advanced so far in recent years that the time may well have come when each separate part of a book like this, which ranges from genetics and physiology to housing and disease, should be written by an expert of its own It is scarcely fair nowadays to expect one man to deal adequately with such a wide field, and in matters concerning animal husbandry what applies in one country may not necessarily apply in another

J A B SMITH

MEDICAL BIOMETEOROLOGY

Medical Biometeorology

Weather, Climate and the Living Organisms By Dr S W Tromp, in co-operation with 26 Contributors Pp xxvii +991 (Amsterdam and London Elsevier Publishing Company, 1963) 120 D fl, 240*s*, 134 D M

THE influence, real or imaginary, of weather on the behaviour of man and animals has been the subject of controversy and consideration by many authorities and individuals ever since the human race began to think The scientific development of the problems, hampered though it was by contributions more conspicuous for their enthusiasm than their logic, has made rapid progress during the past decade, and the author of this volume, together with his twenty-six collaborators, have made a very welcome attempt to summarize what is now known of a very complex subject

Dr S W Tromp is head of the Bioclimatological Research Centre at Leyden in The Netherlands, and his contributors are specialists of high scientific standing in the United States, Germany, Great Britain, Canada, Peru, Australia, The Netherlands and Israel. The book, of nearly a thousand pages, commences with a review of the physical, chemical, air pollution and extra-terrestrial factors of the atmosphere and the methods used in assessing their effects on the living organism Part 4, comprising nearly half the book, entitled "The Effect of Weather, Climate and Season on Man", deals in considerable detail with the meteorological influences on the human being and his semi-artificial living conditions in health and disease Shorter chapters follow discussing effects on animals and insects, and Part 6 deals with the microclimate of space vehicles

The final contribution is of the highest importance, written by Prof F Sargent of the University of Illinois, it discusses the necessity and the organization of graduate training in human biometeorology The urgent need for rapid advances in scientific fields involving two or more disciplines is such that the basic principles stated herein deserve wide recognition The young scientist must be given sound training in one main science followed by a firm working knowledge in the interdisciplinary régime In addition he must be able to work as a member of a team so that specialized training and ability can be combined to solve a problem which is of a multiple scientific nature Most important of all, a student must learn to be able to understand and interpret complex interrelated facts. It must clearly be understood that advances in sciences are not made by the simple collection of endless data, but by the brains of the men who are capable of perceiving the new relationships which can justifiably be deduced from such facts

The last part of the book consists of a very helpful bibliography of more than 4,000 entries The very volume of diverse contributions scattered throughout the scientific journals of the world explains why a book of this nature meets a real need As the author says in his "Retrospect", biometeorologists still have a long way to go before they can solve all the important problems and fully explain the various observations made Nevertheless, the publication of this volume can truly be regarded as a significant step forward on the road towards increased reliable, useful knowledge

The printing and presentation are good, the author deserves our thanks for his work and our admiration for his energy and devotion to his aims His last sentence gives us the clue as to how this can come about—"It is this deeper understanding of the continuous interaction between the living and non-living worlds, which makes biometeorology one of the most fascinating and promising border sciences of the twentieth century"

L P SMITH

THE PRIMARY WORKING GROUP

Organizational Choice

Capabilities of Groups at the Coal Face Under Changing Techniques—The Loss, Re-Discovery and Transformation of a Work Tradition By E L Trist G W Higgin, H Murray and A B Pollock Pp xv+332 (London Tavistock Publications (1959), Ltd, 1963) 48*s* net

IN most low-seam coal-mining areas three main types of mining co-exist the traditional system of single-place working, a conventional system involving the cutting or hewing of longwalls and hand-filling the coal on conveyors, and the attack on longwalls by a composite group with a much higher level of mechanization

In the single-place system the key-figure is the multi-skilled self-supervising face-worker to whom the deputy or foreman stands more in the role of service agent than that of supervisor The face-worker graduates to this position after years of working on supporting jobs and when he has established his right to the commanding position. Under the conventional system a distinct division of labour emerges where specialized tasks are carried out by a number of groups of varying size Each group has separate pay-notes and its own mores, while inter-group rivalry and some hostility are not infrequent Co-ordination and control come directly from management

With the composite longwall system of working the difficulties arising from over-specialized work roles, segregated task groups and lack of group cohesion are successfully overcome There is a common pay-note with an equally shared bonus The working group itself allocates men to shifts and jobs and the result is a multi-skilled commando-like force where all suffer financially if any work is neglected

Organizational Choice is a long-term study by members of the Tavistock Institute of Human Relations, which describes, *inter alia*, investigations into the effects on productivity of the single place, conventional longwall and composite longwall systems of working The conclusions are not unexpected, and, in a truly fascinating way, Trist and his fellow-authors show that where the activities of a primary working group can be planned and controlled by its own members, the only barriers to productivity are those set by physical limitations in man and the environment Over a period of two years, the composite group showed itself not only capable of functioning as a "self-regulating, self-developing social organism", but also able to maintain itself at a high level of productivity throughout the whole period Even more important was that, at the end of the time, the groups were still growing in their capacity to adapt to changes in their task environment and to satisfy the needs of their members What is more significant, however, is that the composite method of working under a fully mechanized system is but a return to the traditional 'butty' system common in coal-mines before the advent of mechanization The wheel has turned almost a full cycle and these investigations show that the ruthless breaking down of jobs without regard to human need and dignity leads only to destructive frustration and a low level of productivity, which is the accompaniment of poor individual and group morale

Apart from a spontaneously generated jargon which characterizes so many Tavistock Institute publications, *Organizational Choice* is a well-written description of a not undramatic story The text unfolds to show a clear design, and this is supported by some illuminating tables and diagrams General conclusions of importance are developed from the specific findings, and all National Coal Board officials should see that the authors' plea for a machine-centred work culture to replace the existing manual work culture could represent the birth of a new attitude to work and workers in the coal-mines The idea of group training of work-groups rather than individuals also has much to commend it It is perhaps unfortunate that details of the present-day pay and incentive schemes have not been included if only to enable responsible management and Trade Union officials to persuade more recalcitrant colleagues that the benefits to the men are not only intangible

So valuable is the book, however, that one wonders whether the authors are doing justice to themselves and their collaborators Their conclusions should be within the reach of all supervisors and workers in the coal-fields of Britain and elsewhere Could their account be turned into film? They might also have indicated other industries and organizations where their findings might have validity. Metal-making rolling and forging? Oil and chemicals? Retail stores? The approach described in this book and the conclusions arrived at by Trist and his colleagues should also form the basis for case-histories wherever managers and supervisors are being trained

T H HAWKINS

SCIENCE AND THE STATE*

PHYSICS - ART

By Prof R. V JONES, C B, C.B.E.

Department of Natural Philosophy, University of Aberdeen

The 1859 British Association Meeting

THE British Association first met in Aberdeen in 1859, and the report of the meeting shows what a great part the Association at that time played both in the world of science and in the life of the nation The Prince Consort was president, and his address was a beacon in the advancement of the status of science in Britain The literature for the meeting included a long list of distinguished visitors from Great Britain and the British Empire, there was also a shorter list of equally distinguished men from other countries, formally but bluntly headed, with Victorian confidence "Foreigners" This confidence was at its peak, still glowing in the triumphs of the Great Exhibition of 1851, and it was a symptom of the energy of the Victorians, and of the enthusiasm of Aberdeen, that when in 1857 the citizens of the city found that they had no building fit to welcome the great assembly of the Association, they floated a private company and subscribed enough capital to build the Music Hall in which Sir Eric Ashby delivered his presidential address to this year's meeting The money was found and the Hall built, all within two years Could we beat that performance to-day ?

The multitude of papers presented at the meeting contained many original results Here again, comparison with our own time shows the 1859 meeting in a most favourable light in Section A, for example, 79 papers were presented, compared with 25 this year There are, of course, reasons why the number has diminished progress and competition in science now preclude the saving-up of major results for an annual meeting But by any standards, the content of the 1859 meeting was remarkable James Clerk Maxwell was a professor of natural philosophy in Aberdeen, and at the meeting he announced his derivation of the law of distribution of molecular velocities in a gas, with Faraday, Kelvin and Joule among his audience

Maxwell, incidentally, was one of the original subscribers to the Music Hall Company, and from time to time small dividends were paid He left Aberdeen in 1860, and died prematurely in 1879, but for long afterwards attempts were made, with Aberdonian honesty, to pay him his dividends In the end, some time in the present century, a desperate advertisement appeared in the Aberdeen local newspaper to the effect "Will anyone who knows the present whereabouts of Mr James Clerk Maxwell please communicate with the undersigned" The advertisement came from the lawyers responsible for the payment of shareholders, because for years they had been sending the dividends to Maxwell at Marischal College, only to have them repeatedly returned with the legend "Not known"

Aberdeen's tendency to forget Maxwell persisted into the 1930's In the brochure produced for the 1934 meeting of the British Association in Aberdeen, his name will not be found among the list of physicists who have been connected with the University of Aberdeen This forgetfulness, since happily corrected, stood in contrast to the attitude towards Kelvin in Glasgow, where Prof Dee found on his arrival in the Department of Natural Philosophy there in 1945 all kinds of Kelvin relics, including a museum display case full of broken glass reverently labelled "Glass broken by Lord Kelvin in an attempt to make a vacuum"

Lyon Playfair

Our attitude towards the great figures of the British Association of the nineteenth century should properly lie between these extremes We do not need to remark every triviality of their everyday lives, but we have every reason to remember with pride and admiration the greatness of their achievements I wish to recall that among the most interesting of all the distinguished men at the 1859 meeting was Lyon Playfair who, at the age of forty-one, was then for the second time the president of the Chemistry Section, and who was to be president of the Association when it next visited Aberdeen in 1885 In his presidential address, Playfair spoke on "Science and the State"[1], and what I propose to do is to see what progress we have since made along the far-seeing lines that he laid down, and to look at some of the new problems that have in the meantime appeared

At the time of his address, Playfair had given nearly fifty years of service both to science and the State, and had thus acquired experience that even now is without parallel He had been a friend and adviser of the Prince Consort since the time of the 1851 Exhibition, and it was natural that he should turn for his theme to the Prince's own address, from which he took as text "We may be justified in hoping that the Legislature and the State will more and more recognize the claims of Science to their attention, so that it may no longer require the begging-box, but speak to the State like a favoured child to its parent, sure of his paternal solicitude for its welfare; that the State will recognize in Science one of its elements of strength and prosperity, to foster which the clearest dictates of self-interest demand".

Science and Education

Playfair started by pointing, as he had so often done before, and as so many of us have done since, to the fact that other countries appeared to value science and education more than Britain did Especially he mentioned the United States, which had reserved "large tracts of its national lands for the promotion of scientific education" This was the origin of the 'land-grant colleges', less-respectfully called the 'cow colleges', which developed into the present State universities that are an important feature of the American educational system Playfair cited with approbation the wisdom of Washington's farewell address to his countrymen "Promote as an object of primary importance institutions for the general diffusion of knowledge In proportion as the structure of a government gives force to public opinion, it is essential that public opinion should be enlightened"

Playfair devoted much of his address to the part that science should play in education, underlining the conclusion[2] of the Duke of Devonshire's Commission on Scientific Instruction in 1873 "Considering the increasing importance of science to the material interests of this country, we cannot but regard its almost total exclusion from the training of the upper and middle classes as little less than a national misfortune".

---

* Substance of an Evening Discourse delivered on September 2 at the meeting of the British Association for the Advancement of Science in Aberdeen

The setting-up of that particular commission had, incidentally, been very largely due to Playfair and a body of like-minded men in the British Association and in the Society of Arts. Most of these men are more familiar to us to-day than Playfair is: Huxley, Kelvin, Ruskin, Herbert Spencer, and Matthew Arnold. But there was one even more forgotten than Playfair, and so perhaps I may be permitted to mention him especially. He was Colonel Alexander Strange, a survey officer of the Royal Engineers, who had read a paper before the 1868 meeting of the British Association, "On the Necessity for State Intervention to secure the Progress of Physical Science". Strange developed his ideas further in a lecture to the Royal United Services Institution in 1871. I quote his far-seeing words[3], as a tribute to an almost forgotten officer who saw far more clearly what his country needed than did the lobbies of the Houses of Parliament or the common-rooms of Oxford and Cambridge:

"The duty of the government with respect to science is one of the questions of the day. No question of equal importance has, perhaps, been more carelessly considered and more heedlessly postponed than this. And, now that a hearing has been obtained for it, neither the governing class nor the masses are qualified to discuss it intelligently; the governing class, because it is for the most part composed of men in whose education, as even the highest education was conducted 30 to 50 years ago, science occupied an insignificant place; and the masses, because they may be taken to be virtually destitute of scientific knowledge. Those who wield, and those who confer, the powers of government being alike incapable of dealing with this question, it devolves on another section of the community to urge its claims to attention.

I must guard myself against the supposition that the proposal I have here advocated comprises all that is necessary for the efficient administration of scientific State affairs. It is only one part of a great system that has to be created. Other parts of the system will, no doubt, receive due attention from the Royal Commission now considering them. But there is one part so important that I feel called on to name it—I mean the appointment of a Minister of Science. He need not necessarily be exclusively devoted to science; he might perhaps, with advantage, have charge of education and fine arts also; but some one in Parliament, directly representing the scientific branches of the national services, has become absolutely indispensable. Another urgent want which, as its scientific character is not purely physical, will probably not be dealt with by the Royal Commission on Science, is that of a high war council—a council of naval and military officers of the greatest professional attainments and distinction, constituted for the purpose of advising the government on the highest problems of strategical science. At present we have not a vestige of anything of the kind, and are consequently, as a military nation, almost destitute of the basis of the military art.

"When we have all scientific national institutions under one Minister of State, advised by a permanent, independent, and highly qualified consultative body, when we have a similar body to advise the Ministers of War and Marine in strategical science, then the fact that, in accordance with our marvellous constitution, these ministers must almost necessarily be men without pretension to a knowledge of the affairs which they administer need cause us no alarm. When these combinations have been, as they assuredly will be, sooner or later, effected, the wealth, resources, and intelligence of the nation, having due scope, will render us unapproachable in the arts of peace, and unconquerable in war, but not till then."

Extraordinarily far-sighted though this was, and even though the Royal Commission of 1871 fully supported the statements of Playfair and Strange, insufficient notice was still taken by the educational public. Another Royal Commission, this time on Technical Instruction, was instituted in 1881, and reported in 1884. It warned that although Britain was still in advance as an industrial nation, other countries would soon pass it unless there was increased attention to science in public education. In the first part of his address, Playfair elaborated on this prognosis, particularly in respect of secondary education. The working classes, he said, were now receiving better instruction in science than the middle classes. This curious result may have been due in part to a working-class demand to know something of the principles behind the machines that they were called on to operate; this demand had already led to the establishment of more than five hundred Mechanics' Institutes in the first half of the century. The other main factor was very probably an unfortunate legacy of Thomas Arnold, the great headmaster of Rugby.

Science and the Schools

Physical science was, in Arnold's opinion: "too great a subject to be studied 'ἐν παρέργῳ' and it must either occupy the chief place in the school curriculum or be left out altogether"[4]. "Rather than have physical science the principal thing in my son's mind", he said, "I would gladly have him think that the sun went round the earth, and that the stars were so many spangles set in the bright blue firmament. Surely the one thing needful for a Christian and an Englishman to study is Christian and moral and political philosophy." And as regards what his curriculum should be: "The study of language seems to me as if it was given for the very purpose of forming the human mind in youth; and the Greek and Latin languages seem to be the very instruments by which this is to be effected". At that point English education took an unfortunate turning; but I cannot help wondering whether Thomas Arnold would have been as rigid as many of his followers in resisting the change to a curriculum in which science was fairly represented.

Playfair and his allies, notably Huxley, fought for a complete revision of the secondary-school curriculum. Especially he attacked in his address the large proportion of the time devoted to classical studies; typically, 12–16 hours a week were given to the classics, and 2–3 hours to science. He cited Milton, Montaigne, Cowley, and Locke as earlier partakers in the assault on classical education although, he said, he recommended milder measures than that of the Emperor of China, Chi Hwangti, who, knowing that his country was held back by undue devotion to the classics of Confucius and Mencius, invited five hundred teachers to bring their copies of these authors to a banquet in Peking, and then buried the teachers alive with their manuscripts in a great pit.

In answer to the critics who had claimed that the boys who had been through a classical education were better than those who had studied science, Playfair retorted by pointing to a selection factor that is still familiar to us to-day: "The comparative failure of the modern side of school education arises from constituting it out of boys who are looked on as classical asses". He blamed such influences as the Civil Service examinations, with their biased marking in favour of the classics, for the reluctance of the schools to change the weighting of their curricula.

Much of the bias has now, of course, been swept away. Physics has, I believe, been for some years the commonest subject taken at the Advanced Level of the Certificate of Education. But the bias persisted for nearly a century after it should have disappeared, despite the points so tellingly made against it by Playfair; and we still see vestiges of its survival—there is no paper on science in the Common Entrance Examination to Public Schools, although there is a compulsory paper in Latin and an optional one in Latin verse. We can still feelingly echo Playfair's apothegm: "The flowers of literature should be cultivated and gathered, though it is not wise to send men into our fields of industry to gather the harvest when they have been taught only to cull the poppies and to push aside the wheat"

It would be both tempting and profitable to examine in more detail the progress of the teaching of science in the schools since Playfair's day Genuine efforts were made in the nineteenth century, even in the primary schools some of my earliest awakening in science came from my mother, who had learnt of such things as the properties of mercury and the characteristics of nitrogenous foods in a London elementary school before 1900 To-day, we are trying more than ever to teach science attractively in the schools, and we should remember especially the support being given for this development by the Nuffield Foundation and by industry

Science and the Universities

Playfair was scarcely less critical of the universities than he had been of the schools, although he commended them for not being so slow in changing their traditions, and for encouraging physical science That he knew them well is obvious from the shrewdness of his observation[5]

"You must not judge of other universities by Oxford and Cambridge for they are exceptional The old English universities have not the same function as the Scotch and Irish universities The former teach men how to spend a thousand a year, while the latter aim at showing men how to make a thousand a year "

He compared the paucity of Government support for universities in Britain with the liberality of the French, German, Swiss and Dutch Governments towards their universities Indeed, he said, by a special clause in the Scottish Universities Bill, the Government had asked Parliament to declare that in no circumstances should the Parliamentary grant ever exceed £40,000 "According to the views of the British Treasury," he said, "there is a finality in science and in expanding knowledge "

Things have, of course, changed a good deal since, and we are now being almost saturated with discussions of the extent to which Government support for higher education should go, and of the proportion of the nation's youth which should be given a university education We are awaiting the report of Lord Robbins's Committee, and I do not wish at this stage to become immersed in statistical estimates There are, however, factors with which I have recently had much to do, notably in the deliberations of a Committee of the Institute of Physics and the Physical Society on some of the problems facing university physics departments in the current expansion programme This Committee has just reported[6], and among the many factors to which it directs attention there is one that I would single out as especially relevant to Playfair's views on science and the State

Universities and Research Establishments

I would first go back to Strange's 1868 paper to the Association In that paper[7], he had proposed "that there should be established a system of national institutions for the sole purpose of advancing science by practical research, *quite apart from teaching it*" Strange's proposal was afterwards supported by the Royal Commission on Scientific Instruction. and Playfair alluded to it in his address

"Such laboratories supported by public money, are as legitimate subjects for expenditure as galleries for pictures or sculpture, but I think that they would not be successful, and would injure science if they failed It would be safer in the meantime if the State assisted universities or well-established colleges to found laboratories of research under their own care Even such a proposal shocks our Chancellor of the Exchequer The widening of the bounds of knowledge, literary or scientific, is the crowning glory of university life Germany unites the functions of teaching and research in the universities, while France keeps them in separate institutions. The former system is best adapted to our habits, but its condition for success is that our science chairs should be greatly increased so that teachers should not be wholly absorbed in the duties of instruction "

Strange and Playfair thus held rather differing ideas on where research should be concentrated They were expressing, in fact, the two sides of an argument that lies at the base of one of our difficulties in physical science in modern Britain The difficulty has arisen because of an intense interaction between science and the State, brought about by the very dependence of our national survival on our technological achievement that Playfair and Strange had both foreseen

It may be vital for us to realize what the difficulty is—so let us look at what happened There were, of course, a few Government scientific institutions before the time of Playfair and Strange, the Royal Observatory at Greenwich being a distinguished example There were also, of course, universities; and despite a contrary argument by Cardinal Newman[8], Playfair held that most of the important British discoveries in science had been made by men who were also teachers As twin results of the efforts of the 1870's and 1880's, new universities were started, and new Government laboratories began to appear The most notable of the latter was the National Physical Laboratory, which opened in 1900 Once again, this was in part due to the belated following of a foreign example, this time that of Germany, where the Physikalisch-Technische Reichsanstalt had been founded in the 1880's, but much of the stimulus for the new laboratory came from the British Association, where Sir Oliver Lodge devoted his presidential address to Section A in 1891 to a strong plea for a "Physical Laboratory precisely comparable to Greenwich Observatory [where] accuracy should be the one great end"

Science and the First World War

The National Physical Laboratory succeeded, and various other Government laboratories were started, but the First World War revealed our national weaknesses resulting from an inadequate awareness of the value of natural science Disquiet among men of science had been simmering for many years After Playfair's death the struggle was carried on, notably under the leadership of Lockyer, whose presidential address to the British Association in 1903 was instrumental in getting the State grant to universities raised from £40,000 in 1902 to £115,000 in 1906 But these were small figures alongside the £500,000 or so provided by the German State for its universities[9] Indignation became so great that on May 3, 1916, a conference was held under the chairmanship of Lord Rayleigh in the rooms of the Linnean Society, following the publication of a memorandum in *The Times* of February 2, 1916, signed by 36 of our most distinguished scientists The meeting was attended by about one hundred and fifty supporters of the memorandum; and some further supporters were unable to pack into the hall They deplored the fact[10] that Britain had "suffered checks since the War began, due directly as well as indirectly to a lack of knowledge on the part of our legislators and administrative officials of what is called 'science' or 'physical science' ", and they pointed out that "In the whole history of British Governments there has only been one Cabinet Minister who was a trained professional man of science—the late Lord Playfair" There were not only men of science supporting the memorandum—to their shining credit, it is worth mentioning that among those who spoke in strong support were Dr Robert Bridges, the poet laureate, Dr Macan, Master of University College, Oxford, Dr Farnell, Rector of Exeter College, Dr Strong, Dean of Christ Church, Dr Shipley, Master of Christ's College, Cambridge, and Mr Nowell Smith, the headmaster of Sherborne School Dr Gow, the headmaster of Westminster School, was also to have spoken, but such was the crowd in the meeting that he was unable to get in These gentlemen were in the main classical scholars, and we should remember them with gratitude alongside Dr Jowett who, as Master of Balliol in an earlier day, had tried against the general run of his fellows to further the cause of science in Oxford

I am not sure of exactly what influence this conference had on Government policy A Committee of the Privy Council for Scientific and Industrial Research had been formed in July 1915 with an advisory council, but things were evidently not moving fast enough for two members of this council, Lord Rayleigh and Sir Charles Parsons, who were among the signatories of the 1916 protest Many influences, of course, were at work The extension of warfare to submarine and aerial operations demanded that scientists be enlisted in support, and new Government establishments began to grow rapidly The Royal Aircraft Establishment at Farnborough, for example, gathered an absolutely brilliant collection of men of science to work on problems of flight, and another distinguished group worked with the Royal Navy on the detection of submarines On the civil side, several research associations came into being

The Inter-War Period

The lessons of the First World War in science, as in international affairs, were only partly learnt Despite various official enquiries, and the formation of the University Grants Committee in 1919, the universities were inadequately supported in science, and the Government establishments became retarded through 'red tape' and parsimony On balance, if one wanted to do research, the universities even with their drawbacks were much more attractive than the establishments In general, the latter were allowed only to undertake research of a specifically applied nature, and the universities were almost the only places where pure research could be pursued A university man's research would inevitably be held up by lack of funds for apparatus and technical support, and by his teaching duties, but so was that of nearly everyone else working in the same field, because they too were working in universities with similar handicaps Thus, one's chance of discovering an interesting result was no less than anybody else's, and so there was little temptation for staff to leave the universities

Effect of the Second World War

The experience of the Second World War brought home to Britain the lessons so imperfectly learnt during 1914–18 Above everything else, the outcome of the Battle of Britain had depended jointly on the devotion of the Royal Air Force and on the imagination of a small band of scientists and engineers This was a lesson that no post-war Government could ignore, and there were plenty of other examples to re-inforce it by the time the War ended, culminating in the release of nuclear energy Now these results had largely been achieved by bringing in scientists from the universities, and seconding them to Government establishments When the War ended, some of these men, perhaps the majority, returned to the universities, but the Government learning from pre-war mistakes, now made its own establishments much more attractive Salaries were made higher than those in the universities, technical assistance was on a much more generous scale, as was also the provision of equipment Some of the differences were defensible matters of national defence could not afford to be handicapped in the way that university research was It should have been equally obvious that university research should be freed from the handicaps of the past But since the Government scientific organizations were administratively nearer to the seat of power, their claims were more clearly heard by the Treasury So the worker in a Government establishment was often able to devote more of his time to research than was his university counterpart and since it had been argued, very reasonably, that the pre-war establishments had been rather dull places because they had little contact with pure research, the better post-war establishments were encouraged to allow a proportion of their staff to spend much of their time on pure research Thus, in some instances, the Government establishments have been able to offer keen research workers better facilities, higher salaries, and a greater proportion of time for pure research than they would find in a university These observations apply particularly to physics, because this branch of science has been involved more than any other in matters of national defence in the past thirty years, but the same thing could happen to any branch of science which should begin to produce results recognized as essential to national survival

Now all this would not matter so much if we were producing enough able physicists (or mathematicians or engineers) to be able to man both the Government establishments and the universities When to these requirements we add those of industry and school-teaching, we find that there are not enough physicists to go round

Science and Industry

Playfair rated industry at its true value to Britain "It may be", he said, "that the engines of Watt and Stephenson will yield in their turn to more economical motors, still they have already expanded the wealth, resources, and even the territories of England, more than all the battles fought by her soldiers, or all the treaties negotiated by her diplomatists" He speculated on the time when coal might be exhausted in England "It may be that the supply of petroleum from America or the borders of the Caspian Sea, will be so easy and cheap that the increased technical education of our operatives may largely overbalance the disadvantages of increased cost in fuel" This was a courageous forecast at a time when oil engines were barely practicable, and when coal was the base for England's greatness

Playfair saw more clearly than most of his contemporaries that the British Empire might be a transient organization, and that the possession of colonies producing cheap supplies of raw materials and providing easy markets for our manufacturers might lull us into doing too little about technical education and industrial development We now all realize that he was right, and neither Government establishments nor universities can survive healthily, unless industry earns enough abroad to provide the necessary money It is therefore essential that industry should use science to the utmost, and that the universities and colleges should provide the scientists and technologists that industry needs Here, incidentally, it is interesting once again to see Playfair hitting the target "But while England has never lacked leaders in science, they have too few followers to risk a rapid march We might create an army to support our leaders in science, as Germany has done, and France is now doing, if education in this country would only mould itself to a scientific age" It has recently been encouraging to read the report of a Working Party of the Federation of British Industries[11], entitled *Civil Research Policy* and published in June, 1963, which shows that the Federation is now very much aware of the need for scientific support in the universities, the Government establishments, and the research associations It calls for proper co-ordination of the overall effort

Demands on Universities

A similar call has come from the Institute of Physics and the Physical Society, who deemed it important to assess the prospective demands on university physics departments in the expansion, in the light of adverse factors such as the drift of staff to Government establishments and to the United States, and to see whether the demands could be met

In the past twenty years, the position of university physics departments has been getting more difficult partly because the teaching load on members of staff has gone up, and partly because the attractions of non-university laboratories have increased As regards the teaching load, the staff/student ratio in science as a whole was rather better than 1/8 in 1939, and worsened to rather less than 1/10 in 1960, according to the University Grants Committee[12] In physics in 1960 the ratio was substantially worse than the average for science, being less than 1/14 While no one can dogmatize about the optimum value of the staff/student ratio, it is clear from the experience of our universities in the past ten years or so that the ratio has fallen too low, judged by the simple but vital criterion of whether the staff find conditions sufficiently attractive to remain in the universities These conditions could be even less attractive in the 'broiler universities' that could result from an uncontrolled attempt to produce university graduates in bulk each with as little flavour as the 'broiler chicken' and supermarket meat that now assault our palates It may be that such devices as teaching machines and other new methods of imparting knowledge may ultimately result in some economy in staff But this prospect, for the advanced subjects at least, is some way off, and even in the United States, which we might expect to be ahead of us in this respect, the staff/student ratio does not appear to be always more economical than our own, at Princeton, for example, the ratio is impressively better than the British average, being about 1 staff to 6 undergraduates

Taking all these factors and others into account, the Institute of Physics report shows that whereas the universities have annually recruited over the past few years a number of physicists equal to about 20 per cent of the national output of Ph D s in physics, they will need to recruit about 40 per cent of the annual output over the next few years, if they are to raise the staff/student ratio to the level where staff will stay in the universities and to meet the demands for physics teaching in the expansion of the universities planned by the University Grants Committee Even though this expansion, from 111,000 students in 1961 to 150,000 by 1967, may be thought by many to be too small, the opinion of a highly representative body of physicists is that it demands the absorption of nearly half of our Ph D output over the next few years The conclusion is important, since it results from what may be the only survey of the national situation in any of the key subjects, and it shows the large scale of effort required

Loss to the United States

The position would not be quite so difficult if Britain did not lose an appreciable fraction of her best science graduates to the United States Thirteen per cent of British Ph D s emigrate permanently, while a similar additional number go to the United States temporarily for post-doctoral work This year, as an external examiner at one of our universities, I set an essay question in the final honours examination, asking the students what they thought about this matter Their views are more important than those of us who are older, because it is primarily the loss of our young research workers that is most serious They did not put pay and standard of living as the paramount attraction It was, of course, important, but their main reasons were the greater liveliness in the United States and the greater public regard for scientists These are not new arguments but the spontaneity and vigour with which the students spoke might have convinced even the Minister for Science that emigration had nothing to do with faults in the American system of education

Teaching and Research

The staff of our expanded universities would not, we hope, be devoting their entire efforts to teaching Indeed, the underlying assumption is that they would have sufficient time to undertake enough research to ensure that their teaching was infused with the spirit of a living subject, and that sufficient research should be going on to make the universities attractive to research workers I just do not believe that teaching at the honours-level can survive without contact with research There are, indeed, some devoted teachers who succeed in inspiring their pupils without undertaking any research themselves, but the numbers of such teachers are in any event too small to undertake more than a fraction of the teaching Much of the teaching must therefore be done by men who want also to carry out research, and I believe it good that this should be so

The question then arises Since the expansion of university teaching must make such demands on the limited numbers of research-trained graduates, how can Britain most effectively use these limited numbers so that their full potential can be realized both in teaching and in research? Here we face a difficulty which by an accident of recent history is greater in Britain than in the United States Whereas the Government establishments have much increased in strength in Britain relative to the universities, the opposite has happened in America The accident was that Britain foresaw the Second World War just in time to enlist science in support of air defence and to recruit scientists to the Government establishments In the United States, far less preparation was undertaken, and the devices that Sir Henry Tizard's mission took to the United States in 1940 were such a surprise that the American authorities decided that the quickest way of exploiting them in the emergency was to set up teams in the universities rather than wait to build up Government establishments The Radiation Laboratory at the Massachusetts Institute of Technology was an outstanding example, its British forerunner, by contrast, was the Telecommunications Research Establishment, a Government establishment The legacy of this accident is that in the United States the universities are now strong, the Government establishments relatively weak In 1960 the position was surveyed by a Presidential committee[13] which thoroughly endorsed the practice of getting the universities to undertake a great proportion of the national research, even that of a defence nature, on the grounds that, as President Eisenhower himself said "The process of basic scientific research and the process of graduate education in universities must be viewed as an integrated task if the nation is to produce the research results and the new scientists that will maintain the leadership of American science"

In Britain, the Government establishments are separated from the universities, and such different conditions have been created in them that the interchange of staff is very restricted the establishments play very little part in teaching the new generation of students This is despite the fact that, owing to smaller numbers in Britain, it is necessary to be even more careful than are the Americans to husband British scientific potential, both for research and for teaching Britain just cannot afford to let this present dichotomy continue It is just as important to realize the teaching potential locked up in the Government establishments as it is to realize the research potential of the universities This is not a problem to be solved piecemeal It needs to be tackled on a national basis, and a better balance sought not only between universities and Government establishments, but also between these and the requirements of industry, the technical colleges and the schools This is one of the most important problems confronting both science and the State in modern Britain Unless it is solved, no substantial expansion can take place, paradoxically, in any subject where there is an acute national interest and since this now involves the very science subjects which are the educational bases of all the others, the whole of the proposed expansion in science is threatened

Science and Defence

The last part of Playfair's address dealt with the theme that the flourishing of abstract science is the condition for progress He had been discussing, he said, the relations of science to the public weal, adding "That is a very old subject to select for the year 1885" Yet we can to-day recognize that it is still worth looking at what he said, partly in admiration of his foresight and partly in regret that the lessons that he preached have still not been entirely learnt

If we look critically at his address, it was so comprehensive that we are challenged to ask the question 'What did he leave out?' For myself, there are two subjects on which I should like to have heard him speak One is that on which a former president of the British Association, Sir Henry Tizard, spoke at the Royal United Services Institution in 1946 This[14] was "Science and the Services" Playfair did not ignore this subject through any question of conscience In the Crimean War he had invented a cipher that bears his name, and he had submitted inventions for incendiary shells and poison-gas shells These were turned down, the latter being rejected on the grounds that they would not be a legitimate method of warfare "Why", he wrote[15] in his *Memoirs*, "a poisonous vapour which would kill men without suffering is to be considered illegitimate warfare is incomprehensible War is destruction, and the more destructive it can be made with the least suffering the sooner will be ended that barbarous method of protecting national rights "

This observation shows that Playfair would have been involved in matters of national defence, had they arisen in his time, and that the omission of them from his address was probably due to their comparative unimportance in the 1880's Yet, as has been seen, some of the drive for science came in fact from the military side As far back as the Renaissance, some of the interest in dynamics sprang from the new problems in ballistics arising from the invention of the cannon In the nineteenth century, Strange's efforts for science were as much devoted to the military applications as they were to the civil and, in the event, it was much more the demands of the two World Wars than anything else that brought about the advancement of science in the public eye This is to be regretted, since the greatness of science lies in its constructive achievements, both intellectual and material, and not in its destructive applications It is, therefore, an unhappy reflexion that it should have taken two vicious wars, rather than the skilled advocacy of men like Playfair, to bring home to mankind the power of science But, accepting the facts as they are, we must congratulate ourselves in Britain that the partnership between science and the Services has been such a cordial one in the past thirty years To quote[14] from Sir Henry Tizard

"The first time, I believe, that scientists were ever called in to study the needs of the Services, as distinct from their wants, was in 1935 and then only as a last resort, The Air Staff were convinced of the inadequacy of existing methods and equipment to defeat air attack on Great Britain, and a committee was established for the scientific survey of air defence I want to emphasize that this committee, although it consisted on paper only of scientists, was in fact from the first a committee of scientists and serving officers, working together

"When I went to Washington in 1940 I found that radar had been independently invented in America about the same time as it had been invented in England We were, however, a very long way ahead in its practical applications to war The reason for this was that scientists and serving officers had combined before the War to study its tactical uses This is the great lesson of the last war "

Sir Henry concluded "What is needed is a scientific staff attached to the central Chiefs of Staff organization that will have no executive duties, nor be overburdened by administration, but will devote its whole time to the study of the influence of advancing scientific knowledge on the problems of defence "

Such an organization as Sir Henry wanted to see is at last coming about The recent White Paper on *Central Organization for Defence* (Cmnd 2097 H M S O , July 1963) [see *Nature*, 199, 1021; 1963] much increases the strength of the Chief Scientific Adviser, and places him on the Defence Council alongside the Chiefs of Staff of the three Services By a wise arrangement the three Services will keep enough of their individualities and traditions to preserve the loyalties which we know from experience to have contributed so much in emergencies to their fighting spirit At the same time, the merging at the higher levels should make for more national and economic planning This had to come, as the Services became more interdependent, and jointly more dependent on the limited resources of science and technology It is thus the growth of science and technology that has been one of the main factors responsible for unifying British Defence Services, and lowering the barriers between them We hope that this same growth may ultimately lower the barriers between nations, so that international relations proceed on a basis of respect by each nation for the constructive achievements of the others

Science and Government

All is not yet well, even with the national organization of science in Britain Attempts are now being made to improve this organization, but they have to face difficulties that would not have existed had organization in Britain been planned at the time when Playfair and Strange were pressing it Instead of having a coherent organization, we have to assimilate various pieces of independent organization which have grown up, not altogether logically, through the absence of a basic plan If we take civil research in electronics, for example we find that responsibility is uneasily divided between the Department of Scientific and Industrial Research and the Ministry of Aviation, while in the important field of computers the Board of Trade has formal responsibility While the Admiralty has its own research establishments, such as the Admiralty Research Laboratory, the Royal Air Force has its research done for it by the Ministry of Aviation, which is also responsible for civil aviation These asymmetries and anomalies arise because individual Ministries were forced to start research projects for themselves because of the absence of a national plan I am certainly not recommending a single elephantine organization for research, since there are many dangers to such a course; but much rationalization of our present arrangements needs to be made, and the very strength of some of the individual growths may be resistant to change, however desirable such change may be It was for Britain, I think, a fortunate source of weakness to Germany in the Second World War that so many clandestine military research centres were set up before German rearmament could come out into the open By the time this occurred many of the individual centres were just too strong and independent to be amalgamated into a coherent organization, so that German research effort could never afterwards be economically directed We are in danger of repeating this error in Britain, for entirely different reasons, and it will take strong leadership from the Ministry for Science if we are to avoid it

Now all these considerations entail that good central planning and leadership are forthcoming, and that great responsibility rests on a relatively small number of men I do not see how to avoid this, but I am not unduly frightened by it Even in limited fields of research, such as elementary particle physics or space investigations, expenditure on a single project may be so great as to make appreciable demands on the national exchequer, and so some degree of central foresight and control is required It is on this general matter of wisely making and implementing scientific policy that I should most like to have heard Playfair speak

His experience of science and Government was quite unrivalled, in this century his mantle fell jointly on Sir Henry Tizard and Lord Cherwell Anyone who had the fortune to know them must be struck by the way that Playfair seems to have embodied the best points of them both In the past few years Sir Charles Snow has made the story of their differences an occasion for investigating the relations of science and Government Actually, their similarities were, from our point of view, much more significant than their differences, and, by the public service that they each unstintingly gave, they both stood for the better incorporation of science and Government, and for the greater recognition of science in national life They were thus both in the Playfair tradition I had the privilege of working with each of them, and from this experience, I venture to give my own thoughts on how decisions on scientific policy might best be taken

Many decisions are taken by open committees, and when time and security considerations allow, this is a reasonable method, even though it sometimes produces a result less sensible than would have been arrived at by any single member of the committee The railway gauge of Ireland, for example, seems to have been settled in this manner[16]—the average of all other national gauges was taken, and the result was 5 ft 3 in the Irish thus had a new gauge, and their rolling stock was not interchangeable with that of any other railway The common agreement necessary for members of a committee to come to a conclusion often does not go far enough, especially in those important decisions where an element of uncertainty and risk has to be accepted This is not always so, and we must remember with gratitude, for example, the courage shown by the Tizard Committee before the Second World War But I have seen many occasions when a committee has been wrong and an individual right, anyone who doubts this has only to read Chatham's last speech on the American War of Independence So while I would accept the committee approach on as public a basis as possible, whenever it is feasible, I am not certain that it is always the best approach

The Scientist in Government

These considerations are especially relevant to the process of incorporating scientific advice into national policy and executive decisions Sir Charles Snow[17], speaking of Lord Cherwell's work in the Second World War, says "We must never tolerate a scientific overlord again"; but Sir Charles proposes no alternative My own view is that, high above the details of controversy, we should be grateful to Sir Winston Churchill for being the first British Prime Minister (if we except Peel, who used Playfair's talent in investigating the Irish potato famine) to rate the contribution of science so highly that he insisted on having personal scientific advice at the highest level The fact is that, especially in matters of defence, executive decisions have often to be taken by individuals If science is not organized so that some of our best-suited men of science are in key administrative positions in Government, then those policy decisions affecting science will be taken by non-scientific men who will at best base their judgments on how they have been convinced by particular scientists as individuals This is certainly not better than having scientific opinion injected at the highest level by an able representative who is himself a man of science, and it could be a good deal worse It may be argued that this task would place great responsibility on the man of science who was selected and the field of science is certainly now so wide that no one man could cover it In his day, and indeed almost right up to the present day, I would have had implicit trust in Lyon Playfair single-handed in this task It would now require more than one man, but surely we are still great enough to produce men of the right calibre

Even so, I would agree with Sir Charles Snow that there is danger in having any man of science in a position of isolated power But the danger really lies much more in the isolation than in the power; and this observation is not peculiar to science—it is general for all aspects of Government How then can we ensure that the individual does not become isolated? For myself, I should try to do this by providing a small forum for each of the principal scientific advisers to the Government, the forum would consist in the main of other men of science as nearly his equals as possible, chosen so that the membership covered in knowledge and experience the full range of his activities The forum should include some relatively young men, older men may be wiser, but their wisdom may well not be enough In the problems that we now face, imagination, energy, and working contact with the most modern technology are essential, in these qualities youth has the advantage, and so the forum should be challenged and stimulated by the presence of some younger men in their thirties or even twenties If the adviser were as wise as he should be, he would consult the forum before taking any key decision, so that while the power to make the decision, or to frame the relevant advice to the Government, was his alone, he would take that decision only after having heard the relevant arguments and he would have to have enough confidence in his decision to be able to justify it in any subsequent face-to-face encounter with his forum. The justification would not be an inquisitorial matter, but would save the individual from the slow drift away from the primary standards of scientific truth and morality that too easily attends the acquisition of unchallenged power Any man brought up in scientific method can scarcely help recognizing scientific truth, whatever the status of man stating it A suitable forum may therefore be the only sanction needed to keep the individual from abusing his power, beyond the sanctions already set by our form of Parliamentary Government I am not claiming, of course, to lay down a rigid procedure for the injection of scientific advice into Government This is a relatively new problem, and none of us knows the full answer, if such an answer exists But I did myself use the procedure I advocate, in my own work in a limited field during the Second World War, and it saved me from error on several occasions, without restricting my speed of operation, I would always use it again

In this story of a few far-sighted men, the part of the British Association for the Advancement of Science has been an honourable one, indeed, as the Prince Consort pointed out, one of its declared aims was "to obtain a more general attention to the objects of Science, and a removal of any disadvantages of a public kind which impede its progress" This aim still exists, and I have therefore directed attention to some of the problems that remain These include the relationship between universities and Government establishments and, more generally, the rational distribution of scientific effort among the universities, establishments, colleges, schools and the vital fields of industry in which we have to earn our national living The need to expand education in science and to reduce the loss to the United States are other parts of the same body of problems Finally, the method of injecting scientific consideration into matters of State requires most careful thought But it is gratifying to find that there is now a general appreciation at least of the existence of these problems and that, on this account, we may be reaching "the end of the beginning". Although Britain has thrown away the lead that men like Bacon and Playfair tried so hard to give her, I believe that Britain still has the talent, the resilience, and the humanity to harmonize the relationship between science and the State This will be not only to their mutual benefit, but also to the good of men as individuals the world over.

SOME ATTITUDES TO VEGETABLES, AND THEIR IMPLICATIONS

By Dr. R HARPER

Department of Psychology, University of Leeds

At a time when, for various reasons, so much emphasis is being placed on the importance of foods it is surprising that so little 'cross-cultural' information has been placed on record about attitudes to foods This article draws together available information from a number of different sources about attitudes to vegetables Vegetables are of special interest because of the wide divergence in attitudes which are encountered. Several different methods of collecting results have been used, including simply counting the number of persons who dislike a particular item or express lack of familiarity with it, or the analysis of views expressed by children about vegetables in the course of a school essay, or—more recently—the use of a simple Hedonic Rating Scale, which gives some indication of the extent to which a particular item is liked or disliked The Hedonic Scale[1], which has a long history behind it, is simply a form of rating scale with the addition of a category of response 'never tried' to allow for this contingency The results of a number of different studies are compared, the potentialities of the Hedonic Scale as a device for routine surveys are considered along with the general implications of the data available from different sources

Two Early Studies

Hall and Hall[2] examined the attitudes of 700 American students in three different universities to some 150 food items Responses were restricted primarily to whether a particular item was disliked or unfamiliar The following information refers to a selection of vegetables from the whole group of foods

Percentage disliked		Percentage unfamiliar	
Parsnips	24	Leeks	65
Egg-plant	22	Okra	51
Hominy	20	Endive	43
Turnips	19	Chard	35
Rutabagas	18	Lentils	31
		Rutabagas	29

For comparison with later studies information about a particular group of five vegetables is also as follows

Percentage disliked		Percentage unfamiliar
Potatoes	1 4	*
Cabbage	5 9	*
Leeks	5 6	64 8 'never tried'
Spinach	8 2	*
Asparagus	3 5	*

(* denotes figures not available)

Vegetables were somewhat arbitrarily divided into strong-juiced versus sweet-juiced, but these two groups overlapped considerably in the extent to which they were disliked

Some regional differences were noted, but similarities between different groups were more noticeable than were differences 50 per cent of the respondents referred to taste as the reason for not liking a particular food, and naturally some of the reasons given were highly personal Women were familiar with more foods than men and had more aversions

Le Gros Clark[3] examined *The School Child's Taste for Vegetables* in war-time England by means of school essays on "The Vegetables we Eat", written by some 432 children The teachers limited their influence to writing a short list of vegetables on the board, including cabbage, sprouts, cauliflower, lettuce, turnips and carrots Table 1 gives a selection of the available data including both the number mentioning and the number disliking a particular vegetable

Many of the children were indifferent to how potatoes were served As a rule, attitudes tended to be rather clearly defined (for or against a particular item) rather than neutral Attitudes to green vegetables (cabbage, sprouts and cauliflower) were fairly uniform, but there were some inconsistencies in the attitudes of particular individuals to the separate items in this group Over the limited age-range considered there were few trends with age The only marked exception again concerned green vegetables in so far as there was a progressive reduction in the percentage disliking them of some 25 per cent when the 10–11-year-olds were compared with the 8–9-year-olds and a further 50 per cent reduction among the small number of 12–13-year-olds who took part in the study No single sensory feature is uniquely associated with

Table 1 ANALYSIS OF DATA FROM SCHOOL ESSAYS ON THE VEGETABLES WE EAT (after ref 3)

	(*N*) No mentioning (out of 432)	Percentage actually disliking	Comments
Potatoes	388	Under 1	
Carrots	379	8	40 liked them raw
Cabbage	329	25	Many individual inconsistencies
Sprouts	305	31	
Cauliflower	302	24	
Onions	262	21	
Leeks	86	51	
Marrow	236	61	
Turnips	270	60	
Parsnips	242	62	(six persons expressed abhorrence—parsnips disliked with monotonous regularity) *
Swedes	220	63	
Broad Beans	142	34	
Haricot Beans	116	20	
Runner Beans	Generally favoured, with exceptions		
Salad vegetables	Generally favoured by about one-third of the children		
Spinach	Referred to occasionally, but many describe it as being strong and bitter		

Note that in all instances where a percentage disliking is quoted, this is calculated in terms of the children who actually mentioned a particular item An unspecifiable adjustment would have to be made to get a better idea of the percentage of the total group who disliked a particular item

* A personal observation about parsnips is relevant here As a child, parsnips stand out in my memory as having an unpleasant, bitter taste Nowadays, they taste rather sweet to me Whether I have changed, or whether the parsnips have changed cannot be resolved Of course if parsnips are stored too long starch turns to sugar anyway

what is liked or disliked but there was a strong tendency for the children to dislike "slimy, mushy, stringy or slippery things". Some bland tastes, especially when combined with these rather distinctive and unpopular textures—as in the case of marrow—also seemed to cause difficulties. Many strong tastes also caused difficulties for some children, and idiosyncrasies were evident in so far as a few children even developed a disliking for peas, and many children found lettuce bitter

Use of the Hedonic Scale

The two investigations outlined here did not involve a systematic attempt to determine the extent to which the various food items were liked or disliked, although some qualitative information naturally emerged from descriptions and comments Dove[4] was probably the first to introduce this more systematic approach and included a number of vegetables in his investigation He was concerned with "Appetite levels of food consumption a technique for measuring foods in terms of their psychological and nutritional values combined" This title directs attention to one of the implications of this whole series of studies in so far as vegetables (and other foods) which may be low in nutrients may be important sources of those nutrients if the foods concerned have a high appeal and are available and assimilated in appreciable quantities

(This observation may prove to be totally irrelevant in the context of an excess of attractive though undesirable foods in conditions of affluence, but such an observation would be scarcely likely to apply to vegetables) In any event, some old people in particular have been known to get their total vitamin C requirement from eating comparatively large amounts of potatoes—about 250 g per day In Dove's pioneer survey 129 individuals expressed their views about 228 food items including 63 vegetables, using the following seven response categories never tried the food—allergic to the food—dislike the food—tolerate only when hungry—desired the food moderately well—considered the food good—considered the food very good Table 2 gives the frequency of responses to seven selected vegetables Results from three separate groups of respondents *A*, *B* and *C* are included Dove has stressed the importance of the number of different ways of preparing various food items For example, he[5] refers to 99 ways of preparing potatoes Even this familiar vegetable may be obtained in a number of different varieties each with their distinctive features and special appeal Different varieties may also serve different purposes For example, in the United Kingdom it has been said that the Majestic variety is particularly suitable for making chips, whereas for other purposes a floury potato is much preferred here, in contrast to a waxy type on the Continent of Europe (Strictly speaking, any statement of this type should be given a date to allow for changes in food habits) The floury Idaho potato is also very popular in restaurants in widely separated parts of the United States, but the fact remains that for the American Serviceman French fried potatoes ('chips' in Britain) are one of the most often and most strongly liked of all vegetables[6] Further attention will be directed later to the precise effects of different methods of preparing the same vegetable or food The fact that the British and the Americans refer to different modes of preparation by the same word 'chips' directs attention to the uncertainties of simply presenting a list of names of food items This difficulty might well be overcome by the more time-consuming procedure of actual taste-testing but it would no longer be possible to evaluate 50–60 food items in a single session

Table 2 DATA RELATING TO SELECTED VEGETABLES (after ref 4)

Vegetable	Group	G or VG	Tolerate	Dislike	Never tried
White potatoes	*A*	84	3	0	0
	B	82	2	4	0
	C	95	0	0	0
Tomatoes	*A*	95	0	0	0
	B	92	4	0	0
	C	88	2	0	0
Cabbage	*A*	92	3	0	0
	B	74	2	4	0
	C	88	2	0	0

	B	42	14	12	16
	C	60	3	8	8
Turnips	*A*	68	13	3	0
	B	60	6	8	4
	C	54	17	0	0
Kohlrabi	*A*	22	14	5	51
	B	8	8	4	72
	C	15	13	5	45
Collards	*A*	0	0	0	95
	B	0	4	0	90
	C	10	2	5	75

Note Percentages quoted do not add up to 100 Nos /Sex *A* 38F, *B* 50F *C* 41M

Table 3 ORDER OF VITAMIN C CONCENTRATION IN A SELECTION OF VEGETABLES AS COMPARED WITH ACTUAL CONTRIBUTION TO DIET, BASED ON AMOUNTS EATEN (after ref 4)

	Percentage contribution from 100 g	Rank	Actual percentage contribution from named source	Rank
Cabbage	143	1	21	3
Collards	100	2	4	7
Broccoli	93	3	18	4
Kohlrabi	71	4	5	6
Turnip	43	5	8	5
Potato	40	6	37	1
Tomato	39	7	23	2

Note in particular that although potatoes and tomatoes are at the bottom of the list in terms of actual vitamin C content, as sources of vitamin C they are at the top of this list

An Exploratory Investigation (United Kingdom, 1956)

IN 1956 a small pilot investigation was undertaken by a group of undergraduates to explore the potentialities of the Hedonic Scale and to provide some provisional information about attitudes to vegetables in the United Kingdom The scale used consisted of only five categories in addition to that of 'never tried' Fifty people of different ages, selected according to availability, gave their views on about 23 vegetables and a selection of the data is given in Table 4

Although the number of respondents is too small to warrant the presentation of a detailed analysis some interesting conclusions emerged Without considering their statistical significance the following points may be noted

(1) Many vegetables, including peas, lettuce, brussels sprouts, carrots, potatoes and cabbage, gave no indication at all of changes with age

(2) Spinach also showed little change with age, but in contrast to the more recent market research survey (see following) opinions about spinach were about equally divided and formed a bimodal distribution

(3) With increasing age, respondents' attitudes became more favourable to parsnips, broad beans and kale, and in the case of kale increasing age brought noticeably increasing familiarity.

(4) Asparagus and artichokes show a similar increase in familiarity with increasing age, but in the case of artichokes, attitudes continued to be fairly well divided, whereas among the over-sixties group no one said they disliked asparagus

Table 4 SELECTED DATA FROM SMALL-SCALE PILOT STUDY
(U K , 1956—50 respondents)

	Like		Neutral	Dislike		Never tried
	very	moderate		moderate	very	
Tomatoes (raw)	62	26	2	4	6	0
Potatoes	40	38	20	2	0	0
Cabbage	36	32	14	14	4	0
Brussels sprouts	50	28	4	10	4	4
Parsnips	22	20	10	12	28	8
Broccoli	14	20	4	6	8	24
Kale	10	14	10	2	6	58
Onions (boiled)	44	14	14	8	12	8
Leeks	24	24	10	8	16	18
Spinach	10	22	2	12	28	26
Artichokes	4	8	4	2	14	68
Asparagus	16	18	4	4	10	44
Corn on the cob (included for comparison)	6	4	8	6	4	72

Quartermaster Food and Container Institute

(1) *Preliminary report (1953)* The Hedonic Scale has now been in regular use by the Food Acceptance Branch of the (U S) Quartermaster Food and Container Institute for the Armed Forces for at least ten years Some eight separate surveys have been carried out with samples of between 3,000 and 6,000 in each investigation Methodological investigations have been included, and these have dealt with such questions as the largest number of items which can reasonably be included on a single occasion, how many categories of response should be permitted, what are the most appropriate verbal formulations of these categories A preliminary report of the first few surveys was presented by Wood and Peryam[7] The number of food items on the forms was limited to 60 or less and a nine-point scale covered the 'Hedonic range' from 'like extremely' to 'dislike extremely', with the additional category 'never tried' The main conclusions include the following

(*a*) There was a marked degree of consistency between the different surveys For example, the 'percentage disliked' ranged from 2 8 to 4 4 for fresh sliced tomatoes, whereas buttered turnips ranged from 40 2 to 51 4, these closely grouped figures for each distinct item point to the stability of the technique

(*b*) A distinction was made between items with 'good acceptance characteristics' and those with 'poor acceptance characteristics' The 'good' group included foods which are disliked by less than 10 per cent of the respondents, the 'poor' group are disliked by 40 per cent or more

(*c*) Vegetables as a class were at the bottom of the list in order of acceptability with only 15 per cent 'good' items and as many as 26 per cent 'poor' items

(*d*) There were 12 vegetables in the 'good' groups and these consisted of only five different items prepared in different ways, that is tomatoes, potatoes, green peas, corn on the cob, green beans

(*e*) Similarly, the 20 vegetables in the 'poor' or 'problem group' consisted of 11 different items prepared in different ways These included squash, parsnips, brussels sprouts, egg-plant, broccoli, spinach, turnips, rutabagas, cauliflower

(*f*) As a general rule, there was no uniformity of opinion about what is disliked, only about what is liked

(2) *Main report (1960)* The most extensive report on attitudes to foods is contained in the 160-page document prepared by Peryam *et al*[6] for the Quartermaster Food and Container Institute for the Armed Forces in Chicago This report combined the results of eight different surveys carried out between 1950 and 1954 The number of food items in a single survey ranged mostly between 45 and 55 In addition to the response category of 'never tried' the following categories were used like extremely—like very much—like moderately—neither like nor dislike—dislike slightly—dislike moderately—dislike very much—dislike extremely These categories were assigned numbers and simply averaged Various possible forms of numerical transformation were considered but these were rejected either on theoretical or on practical grounds Detailed results about individual items are not given in this report so that comparisons with other studies are to that extent restricted The most satisfactory way of presenting the data is to report the 'mean preference values', the 'centile rank', and the 'percentage not tried', for a selection of vegetables (Table 5)

Table 5 ATTITUDES TO SELECTED VEGETABLES
(In rough hierarchical order U S data from ref 8)

	Mean preference	Centile rank	Percentage not tried	
Fresh buttered corn on the cob	8 0	96	1	
White potatoes				
Baked	6 7	55	1	White potatoes appear in 16 modes of preparation ranging from 'mean preference values' of 5 8 (boiled in their skin) to 8 2 (french fried potatoes, i e , chips)
Creamed	6 9	63	2	
French fried (chips)	8 2	97	1	
Mashed	7 6	86	1	
Fresh sliced tomatoes	7 9	94	1	
Fresh grilled tomatoes	6 4	40	12	
Brussels sprouts	4 8	6	10	
Cabbage (boiled)	5 5	16	4	
Cabbage (baked with cheese)	4 3	2	30	
Carrots	5 3 to 5 9	13 to 32	4 to 11	According to mode of preparation
Broccoli	4 6 to 5 6	4 to 18	16 to 38	According to mode of preparation
Turnips	4 6 to 5 0	4 to 8	8 to 11	According to mode of preparation
Rutabagas	4 7	5	39	
Spinach	4 7 to 4 8	5 to 6	5 to 37	According to mode of preparation
Asparagus	4 2 to 4 9	2 to 6	4 to 17	According to mode of preparation
Cauliflower with cheese sauce	4 1	1	12	

Strictly speaking, the mean preference values are the average ratings on the like – dislike scale These ranged from 8 2 for the most popular item to 4 1 for the least Somewhat surprisingly (to me) one of the least popular items was cauliflower with cheese sauce, but perhaps this particular dish is one which is difficult to prepare properly for mass, as opposed to individual, serving

Cauliflower with cheese sauce was at the bottom of the hierarchy with a centile rank 1 The meaning of centile ranks is self-evident, but for clarity a centile rank of 96 would simply mean that only 4 per cent of all items classified would be liked more (on the average) than this one With the exception of broccoli, cabbage baked with cheese and spinach, most of the items included in Table 5 show surprisingly high acceptance characteristics Examples in which information is quoted about more than one mode of preparation indicate just how important this can be Thus, for example, baked white potato (presumably this refers to the Idaho potato) shows a mean rating of 6 7 and a centile rank of 55, whereas French fried potatoes (chips) were extremely popular with an average rating of 8 2 and a centile rank of 97 Note also the very considerable shift when the position of fresh sliced tomatoes is compared with that of fresh grilled tomatoes

Table 6 MASS OBSERVATION (PILOT SURVEY, SPRING 1962)

Mass Observation Study, 1962

The final study noted in this series is in some respects still a pilot investigation in so far as only five vegetables are included The data were collected by Mass Observation, Ltd (London), through the co-operation of Mr L R England In the course of a routine enquiry in the spring of 1962 questions about attitudes to these five vegetables were answered by some 2,000 respondents selected according to usual practices taking account of age, sex, marital status, and socio-economic status and other basic conditions A summary of the main conclusions is given in Table 6

Again, only the more striking observations are emphasized The investigation was restricted to questions about potatoes, cabbage, leeks, spinach and asparagus These were selected in the light of previous experience so as to include the widest possible range of variation in types and patterns of responses, with a view to relating these to the distinctive sub-classes in the sample In this case as few as 1 per cent (or less) of all respondents strongly disliked any of these vegetables This is in marked contrast with the high frequency with which spinach was disliked (28 per cent) in the previous British sample, with its bimodal characteristics Restricting attention here to the 'like very much' category of response the following points stand out

(1) Potatoes show no change at all with age

(2) Whereas the 'like very much' response shows a slight and gradual increase with age of the respondent groups in the remaining instances (that is, other than potatoes) in no case is this trend marked

(3) Sex differences are trivial

(4) Changes with marital status mostly follow the sequence, single, married, widowed and divorced, in increasing order of 'like very much' response Since these trends are very much the same as those with age, perhaps there is some confusion (confounding) of the effects of age and marital status

(5) Socio-economic status only slightly affects attitudes to cabbage and potatoes As might be expected, this variable shows greatest effect on the 'like very much' response for asparagus, varying from 34 per cent for class *AB* to a mere 3 per cent for class *DE* Similar though less marked effects are to be seen with spinach

(6) With the possible exception of its effect on leeks, town size has only a trivial effect on the 'like very much' response

(7) There is no regional variation in 'like very much' response for potatoes

(8) The most marked regional variation is to be found with leeks in the very high frequency of 'like very much' response in Scotland (65 per cent) as opposed to the low value of 18 per cent in the north and east

(9) London and the south-east show the greatest frequency of 'like very much' response for spinach (18–23 per cent) as compared with the north, the north-west and Scotland all with a frequency of 6 per cent

(10) Only in the case of the more unusual vegetables in the group (spinach and asparagus) is there any suggested association to link frequency of 'eating out' in a positive manner with the frequency with which a particular item is liked

(11) Finally, there is in general an inverse relationship between the frequency with which a particular item is liked and its unfamiliarity

The available results have been presented in sufficient detail to make it unnecessary to recapitulate points of detail What, then, are the main conclusions to be drawn from the collation of the information from these very different sources ? Points of special interest include the following

(a) In practically all these investigations potatoes are widely familiar, usually liked and only rarely disliked

(b) Although exact figures for particular vegetables may vary considerably from one investigation to another, with some exceptions relative positions show a considerable measure of concurrence

(c) Comparisons are not simple to make, in view of the fact that no single index provides full and adequate information about a particular vegetable In practice, other variables not discussed here have to be considered in attempts to predict patterns of acceptance

(d) In this context note may be taken of the report by Pilgrim[8] or Pilgrim and Kamen[9] that about 75 per cent of the variability in acceptance of a wide range of foods in the Army situation can be predicted by three variables These were the average Hedonic rating, the satiety value or 'fillingness' of a particular food, and its basic nutrients (protein and fat) This particular observation does not refer exclusively to vegetables but to the complete range of items in the American Army surveys

(e) In particular, this work stresses the potential value of the Hedonic Scale and its use as a method of distinguishing between different foods and vegetables They point to the need for more extensive surveys in the United Kingdom, and to the possibility of making regular comparisons to trace out changes with time in patterns of likes and dislikes

FREQUENCIES FOR RADIO ASTRONOMY AND SPACE SCIENCE

By Dr R L SMITH-ROSE, C B.E.

President, International Scientific Radio Union

FOR several centuries astronomers have been exploring the heavens with the aid of optical telescopes which have been steadily developed to give greater resolving power and precision of observation In more recent times, the astronomer has increased the facilities available to him by the aid of photographical and other recording techniques, thereby extending the range of wave-lengths under observation to include the infra-red and ultra-violet portions of the spectrum Even so, the basic range of wave-lengths available for use by the optical astronomer is limited to approximately the band 1,000–30,000 Å, corresponding to wave-lengths from 10^{-7} to 3×10^{-6} m (or frequencies from 3×10^{15} to 10^{14} c/s) The development of radio astronomy has more than trebled the extent of the electromagnetic wave spectrum now available for scientific research, the frequencies in present-day use ranging from 2 5 to more than 30,000 Mc/s (wave-lengths 120 m to less than 1 cm)

Radio Frequency Allocation

In the past decade or so, the use of radio waves for all purposes such as communication, navigation, broadcasting and television has expanded on an enormous scale, with a consequent increasing demand for allocations of various portions of the radio-frequency spectrum It has therefore become essential for scientists engaged in radio astronomy or space science to establish their claim to the protection of certain bands of frequencies for their use in experimental research

For this purpose, an Inter-Union Committee on Frequency Allocations for Radio Astronomy and Space Science (IUCAF) was formed in 1960 under the auspices of the International Council of Scientific Unions, to examine in detail the number and width of the various frequency channels in which protection from interference is desired, and to report its conclusions to the International Telecommunication Union and its International Frequency Registration Board The Inter-Union Committee consists of representatives of the three international scientific bodies concerned (namely, the International Scientific Radio Union, the International Astronomical Union and the International Committee on Space Research), together with members of the International Council of Scientific Unions, the International Telecommunications Union and the International Frequency Registration Board, and with one or more independent consultants, who are specially experienced in the international radio field Dr J F Denisse of the Observatoire de Paris is the chairman, and Dr R L Smith-Rose is the Secretary-General

The Committee on Frequency Allocations for Radio Astronomy has given serious study to the problem of frequency protection for radio astronomy and space science, and its representatives have participated in both study group meetings and the recent (1963) Plenary Assembly of the Comité Consultatif International des Radio-communications, at which the technical issues involved have been discussed on an international scale Both radio astronomy and space research are recognized services within the sphere of the International Telecommunication Union, and some progress was made at Geneva in 1959 towards ensuring the protection of frequencies required for such services

At the forthcoming Extraordinary Administrative Radio Conference of the International Telecommunications Union, which opens at Geneva on October 7, the rapid progress made in recent years in both radio astronomy and space science and communications will be reviewed in detail, in order that the allocation of specific bands of frequencies may be made more definite

Radio Astronomy

The International Telecommunication Union in its Geneva, 1959, Radio Regulations recognizes the Radio Astronomy Service in the following two definitions

"No 74 *Radio Astronomy* Astronomy based on the reception of waves of cosmic origin",

"No 75 *Radio Astronomy Service* A service involving the use of radio astronomy"

It should be noted that the Radio Astronomy Service differs from all other radio services in two important respects (a) it does not itself originate any radio waves and therefore causes no interference to any other service, (b) a large proportion of its operation is conducted by the use of reception techniques, which are several orders of magnitude more sensitive than those used in other radio services

The radio astronomer continues to improve his reception techniques, aerial systems and receiving apparatus, in order to obtain the utmost sensitivity for recording the very weak signals forming the various radiations he is studying The conduct of this work involves him in the development and construction of very expensive equipment, and it is important to ensure that the use of this apparatus should not be unduly impaired by interference from other radio services

In order to pursue his scientific research successfully, the radio astronomer seeks protection from interference, first, in a number of bands of frequencies distributed at approximately harmonic intervals throughout the spectrum, and secondly, more complete and specific protection for the exact frequency bands in which natural radiation from, or absorption in, cosmic gases is known or expected to occur An example of the latter is the emission line of hydrogen at 1,400–1,427 Mc/s, which is already given an exclusive allocation in the existing Radio Regulations (1959) In all other cases in these Regulations, reference to frequencies for radio astronomy is made on a basis of sharing with other radio services What is now sought is an improved measure of protection for a number of these frequencies distributed throughout the spectrum, from the guard bands associated with the standard frequencies of 2 5, 5, 10, 15, 20, and 25 Mc/s, to a number of other frequencies at or near the values of 40, 80, 150, 408, 610, 2,700 and 5,000 Mc/s The widths of the bands in which, so far as practicable, an exclusive allocation is desired at these frequencies, range from 0 5 Mc/s at the lower end to 10 Mc/s at the upper end of the spectrum In addition, and to provide for future developments in research, it is requested that radio astronomy should be regarded as a primary service in four higher regions of the spectrum at 10 6, 15 4, 19 4 and 31 5 Gc/s, where bandwidths ranging from 0 1 to 0 3 Gc/s are suggested as being necessary for the efficient pursuit of research with the most advanced type of apparatus at present available

Space Research

The need of the space research scientist for protection of radio frequencies is somewhat different from that of the radio astronomer Some satellites are already in use for direct application to the extension of world-wide communications Many other satellites are, however, being placed in orbit around the Earth with the view of extending our knowledge of the upper atmosphere at increasingly great heights, and to measure various physical quantities in outer space, such as solar radiation, cosmic rays, and the density and orbits of electrons trapped in belts determined by the Earth's magnetic field In some cases the frequencies required here are for control of instruments in the satellite or for locating it during its orbit, and, in such instances, the frequencies could be conveniently shared with the corresponding requirements of, say, communications satellites But, bearing in mind the inaccessibility of the scientific equipment carried in the space vehicle and the need to use the measuring equipment for the maximum proportion of the available time, it is important that the results of the scientific measurements can be communicated to the ground controlling station or laboratory with the minimum of delay or interference It is thus desirable that a number of bands of frequencies in appropriate parts of the spectrum should be allocated, without danger of interference, to the needs of scientific research being conducted with the aid of satellites in orbit

At the recent meeting of the International Committee on Space Research (COSPAR) in Warsaw, the following general resolution was adopted "Considering that the transmission of data from space vehicles to the ground is essential to the use of such vehicles in space research, COSPAR recommends that through IUCAF every effort should be made to guarantee the continued allocation of suitable frequency bands for this purpose "

While in some cases frequencies required by those concerned with communications by means of satellites can be shared with the scientist interested solely in scientific measurements, in many instances it is desirable to have separate allocations, so far as is practicable, in order that the elaborate and expensive equipment used in space research can be used to the utmost extent It is thus desired that bands at approximately the following points in the spectrum should continue to be available for the purposes of space research on at least a primary, if not on an exclusive, basis 136, 400, 1,427, 1,700 and 2,300 Mc/s, and 5 2, 8 5, 15 2 and 31 5 Gc/s A number of other frequencies are also required for tracking and controlling satellites and for communication and telemetry services, but in some or most of these cases the actual frequency bands may be allocated on a shared basis among the various users

Conclusion

It will be seen from the foregoing brief survey that the rapidity with which advances in both radio astronomy and space science are taking place at the present time renders it most important that careful consideration should be given to the allocation, on either an exclusive or on a primary basis, of various bands of frequencies within the radio spectrum The forthcoming Conference at Geneva will have the most difficult task of debating the claims of the various users, anxious to advance radio astronomy and space science as well as the practical operation of world-wide communications by means of Earth satellites But it is the decisions and recommendations of this Conference that will determine the ease with which scientists will be able to pursue their work with the maximum degree of protection from interference from other radio services

OBITUARIES

Prof. E D Hughes, F.R S.

THE untimely death in London on June 30, after a short illness, of Prof E D Hughes, head of the William Ramsay and Ralph Forster Laboratories, and professor of chemistry in University College, London, deprives British science of a man of wisdom and authority at the height of his powers

Edward David Hughes was born on June 18, 1906, of a farming family in Criccieth He studied chemistry at the University College of North Wales, at Bangor, under Prof K J P Orton, whose pioneering work in mechanistic organic chemistry inspired his early enthusiasm for this field His first scientific papers, on kinetic aspects of keto-enol tautomerism, were published with Orton and with H B Watson He took a Ph D degree of the University of Wales in 1930, and in that year he joined Prof C K Ingold in the Chemistry Department of University College, London, as a post-doctoral Fellow In 1936 he became Ramsay Memorial Fellow, and then successively assistant lecturer and lecturer on the staff of that Department This period marked the beginning of the long scientific collaboration which, continuing as it has until his death, is almost without parallel in the history of English science, and inextricably links the names of Hughes and Ingold as the foremost contributors to a change in approach to organic chemistry, which now is manifest both in the terminology and teaching of the subject, and at the forefront of progress in the field

His first investigations at University College, London, were in the field of nucleophilic displacement and elimination reactions The simple concept that several limiting mechanisms for such reactions could be identified and characterized kinetically led quickly to the recognition of fundamental patterns of behaviour which until then had been obscured by apparently conflicting observations Perhaps the major triumph of this period was the elucidation of the main factors determining whether racemization, retention or inversion accompanies nucleophilic displacement at a saturated carbon atom—the problem of the 'Walden inversion' His brilliant reviews in the *Discussions of the Faraday Society* in 1937 and 1941 still provide the fundamental basis of any mechanistic account of these reactions They anticipate also many of the later developments in this field, stereochemical, structural and environmental factors, determining the course of these reactions and the rearrangements which can accompany them, are all discussed in these early summaries, though the elaboration of details required many years of later investigation, to which he and his associates no less than other workers in the field have since contributed

From 1939 he was one of a very small staff maintaining the Department of Chemistry of University College, London, through its evacuation to Aberystwyth and Bangor In 1943 he was appointed to the chair of chemistry in the University College of North Wales at Bangor where he had first studied There he spent five years, and was responsible for the rapid post-war rebuilding and expansion of his Department At the same time he gathered around him a group of enthusiasts in the application of isotopes to the study of reaction mechanisms Their pioneering work on the large-scale separation of the heavy isotope of oxygen now has fruitful offshoots in several departments and countries

Through this period, Hughes maintained his interest and participation in the work in progress in the Chemistry Department of University College, London His direct and critical approach led during these years towards simplification of the interpretation of the kinetic forms observed for aromatic substitution, and to the general acceptance of the view that the nitronium ion is the most important entity involved in aromatic nitration

In 1948 he was appointed professor of chemistry at University College, London Here he remained until his death His scientific distinction was marked in 1949 by his election to fellowship of the Royal Society In 1961 he became head of the Department of Chemistry at University College, London His contributions to the elucidation of reaction mechanism ranged in these years over a wide field He initiated important and imaginative studies of structural and stereochemical effects in nucleophilic and aliphatic replacement reactions, of Wagner-Meerwein and related rearrangements, of anionotropic rearrangements, of electrophilic aromatic and aliphatic substitution, of aromatic rearrangements, and of prototropic shifts Alongside these developments he maintained a policy of encouraging and fostering independence in his younger colleagues, who owe a great debt to his generosity and to his faith in their ability and promise

In 1961 he undertook editorship of a series of monographs to be published by Elsevier on special topics in physical organic chemistry, the first of these was at the proof stage at the time of his death

His services to academic life, which were marked by his election to fellowship of the University of Wales and of University College, London, were by no means solely in the field of research A valued teacher and colleague both at Bangor and at University College, London, where he was dean of the Faculty of Science from 1958 until 1961, he contributed also in a most valuable and important way as an appointed teacher of the University of London, particularly through his chairmanship (1955–60) of the University Board of Studies in Chemistry Here his wise and efficient guidance gained him many friends, and he will be much missed from the academic councils of the University during the times of change ahead He was greatly in demand as external examiner for first degrees and for higher degrees of universities throughout Britain He performed an extremely important task as honorary secretary (1949–61) and then as chairman of the Advisory Council of the Ramsay Memorial Fellowship Trust, and on committees of selection for Imperial Chemical Industries, Ltd, and other senior research fellowships, where his judgment, common-sense and powers of assessment were regarded highly.

Outside the University he played many important parts He was a governor of the Northern Polytechnic (1950–60) He was a Fellow (1938) and member of the Council (1961–63) of the Royal Institute of Chemistry, and acted for the Institute as assessor in organic chemistry for Higher National Certificates and Diplomas, and as a special examiner, he was honoured by the Society as a Meldola Medallist in 1936 Perhaps his greatest contribution, however, was to the Chemical Society, to the publications of which he personally contributed so much He served on almost every sub-committee of this great Society, being chairman of the Library Committee from 1959 onwards, an honorary secretary from 1950 until 1956, and a vice-president (1956–59) He was honorary secretary of the Chemical Council (1953–55)

Hughes's scientific lifetime has seen an enormous change in organic chemistry All its many aspects have been affected by the realization that the complicated patterns of yield and reactivity can be interpreted and already in part predicted in terms of the accessibility of the various transition states leading from starting-materials to products Few have contributed to the acceptance of this approach, bitterly contested as it has been, more than Hughes His work has always been characterized by steadfast belief in the importance of mechanistic investigations, an insistence on experimental verification of each point as it has come under scrutiny, and an intuitive recognition of the quality of crucial experimental observations

He was a man of outstanding humanity His actions and his advice led directly to the heart of any problem through clear recognition of general principles His friends will remember him for his deep sense of loyalty, for his unshirking sense of responsibility, and for his devotion to the Department where so much of his work was done

In 1934 he married Ray Fortune Christine, daughter of the Rev Ll Davies, of Brecon She survives him with their daughter P B D DE LA MARE

Dr. Annie Porter

PARASITOLOGISTS the world over will mourn the loss of Annie Porter, who died in London at the advanced age of eighty-three on May 9 after a protracted and debilitating illness

Born at Shoreham-on-Sea, Sussex, on February 20, 1880, Annie was the elder daughter of Samuel Porter The family early moved to Brighton where she received her school education, whence she proceeded to University College, London There her first love was mycology—a subject in which she retained an interest throughout her life—although animal parasitology, and especially protozoology, demanded most of her professional time in later years

From University College she proceeded in 1914 for a time to the Quick Laboratory in Cambridge, where she met and worked with H B Fantham (and whom she married in 1915) At Cambridge Dr Porter held a Beit Memorial research fellowship for two years and taught as an assistant helminthologist

In 1917 she accompanied her husband to Johannesburg and became head of the department of parasitology in the South African Institute for Medical Research, serving also as senior lecturer in parasitology in the University of the Witwatersrand and as examiner in zoology and animal parasitology at both institutions She remained in South Africa until 1933 when she accompanied her husband to Canada, where she remained until 1938 as research associate in zoology at McGill University, Montreal On the death of her husband (during October 1937) she was invited by the secretary of the Zoological Society of London (Dr (now Sir) Julian Huxley) to become honorary parasitologist at Regent's Park, a post she filled with great success until a few months prior to her death

The furtherance of zoology and especially animal parasitology was almost the sole interest in Annie Porter's long life Always ready to help anyone interested in animals, she will long be remembered by her many pupils and friends who are now widely scattered over the globe Her dedication to zoological science transcended all other interests and amounted to a passion when stimulating her co-workers in the several team projects with which she was associated

Her early interest in mycology found expression during the lean periods of the Second World War when she combed the areas around her home for edible fungi, samples of which she generously bestowed on her friends She spent long hours propagating the edible species by spreading their spores in suitable localities in Regent's Park

Apart from her scientific work Dr Porter devoted her time to social welfare and particularly to the education of spastic children, for whom once a year she borrowed live animals from the Zoo for demonstration

Out of her large estate in Great Britain, Dr Porter willed £10,000 to Christ's College, Cambridge, to endow a research scholarship in animal parasitology and protozoology, £5,000 each to University College and to the Zoological Society of London for similar research scholarships, besides £5,000 to the University of the Witwatersrand for a research scholarship "to be held in any University in the British Empire" and £1,000 to McGill University for a research scholarship W C OSMAN HILL

NEWS and VIEWS

The U.S. National Science Foundation: Dr Alan T. Waterman

ON the retirement of Dr Alan T Waterman as first director of the National Science Foundation, the three Presidents of the United States under whom he had served paid tribute to his skilled leadership in establishing the Foundation and guiding it through the crucial years of its existence as a Federal agency in support of basic research and education in the sciences The statements of the three Presidents, as well as tributes from the scientific community, were read at a dinner given for Dr and Mrs Waterman by the National Science Board on June 21, 1963 President Kennedy observed "Through the work of the Foundation in sponsoring basic research, the Nation has embarked on exciting and critical adventures in science that will contribute importantly to human progress The NSF has helped extend our horizons to the innermost workings of man and his society and the outermost reaches of our planet and the universe" Dr Waterman, who continues as a consultant to the Foundation, is also president of the American Association for the Advancement of Science, and next year will become chairman of the Board of Directors Dr Waterman has deferred for the time being further plans for the future until he avails himself of the holiday which he consistently neglected in order to devote himself to the work of the National Science Foundation

Dr. Leland J. Haworth

DR LELAND J HAWORTH succeeded Dr Alan T Waterman as director of the National Science Foundation on July 1 He has been one of the five commissioners of the U S Atomic Energy Commission since 1961 Prior to his appointment as commissioner, Dr Haworth was associated with the Brookhaven National Laboratory, one of the United States' major facilities devoted to high-energy physics He became director of the Laboratory in 1948, and in 1960 he was, in addition, made president of Associated Universities, Inc, a non-profit corporation of nine eastern universities which operates the Laboratory for the U S Atomic Energy Commission and the National Radio Astronomy Observatory for the National Science Foundation A native of the Middle West, Dr Haworth was educated at the University of Indiana, where he received his A M degree, and at the University of Wisconsin, where he was awarded his doctorate in physics in 1931 During 1938–47 he was professor of physics in the University of Illinois During the Second World War he was on leave of absence from Illinois to work on radar development at the Radiation Laboratory of the Massachusetts Institute of Technology Dr Haworth's intimate knowledge of Government research and development problems has been further enhanced by membership of a number of advisory committees and panels His most recent personal research interests include high-energy physics, and high-energy accelerator design In earlier years he worked on secondary emission of electrons, Joule–Thomson effects at very low temperatures, nuclear physics, and electronics

Mathematical Physics at Birmingham: Prof T H. R Skyrme

MR T H R SKYRME has been appointed to the chair of mathematical physics at the University of Birmingham as from October 1, 1964 Mr Skyrme succeeds, as professor and head of the Department of Mathematical Physics, Prof R E Peierls, who has been appointed Wykeham professor of physics in the University of Oxford (see *Nature*, 196, 1038, 1962) Mr Skyrme's academic career started with scholarships at Eton and at Trinity College, Cambridge, where after taking a double first in mathematics he became a Fellow of his College During the Second World War he was with Prof Peierls for two years as a member of a British mission sent to work with American scientists in New York and later in New Mexico, he returned to the United Kingdom with Prof Peierls as a Research Fellow in the Department of which he is now to be the head Here he met and married Dr Dorothy Millest, at that time lecturer in the Department of Physics Since leaving Birmingham in 1948, Mr Skyrme and his wife have been on the staff of the Atomic Energy Establishment, Harwell, except for two years when he held fellowships at the Massachusetts Institute of Technology and Princeton, a period when he was a visiting professor at the University of Pennsylvania, and the time since 1962 when they have been teaching at the University of Malaya Thus Mr Skyrme, who is aged forty, goes to Birmingham in 1964 with experience of eight universities and research institutes in three continents He has carried out research in the theory of atomic nuclei and of sub-nuclear particles, especially in field theory

Memorial to the Late Dr. A. T. R. Mattick, C.B.E.

COLLEAGUES and friends of the late Dr. A. T. R. Mattick, for many years head of the Bacteriology Department and deputy director of the National Institute for Research in Dairying, University of Reading, wish that some form of memorial be established to commemorate his work and perpetuate his name. Everyone who knew Dr. Mattick will be aware that he set himself high standards in his scientific work and in its presentation. They will also remember that he always had in the forefront of his mind the benefits to the Institute's research programme which came from discussion with scientists in other research centres both at home and abroad. It is proposed, therefore, to establish a memorial fund, the income from which, in the absence of financial support from other sources, would be used to enable members of the research staff of the Institute to visit research centres either in the United Kingdom or abroad or to attend specialist conferences. It might also be appropriate on occasion to invite a distinguished scientist to give a memorial lecture on a topic which would be of interest to people connected with dairying. Individuals and organizations within the dairy industry who have reason to be grateful to Dr. Mattick for his help and guidance would no doubt wish to be associated with this proposal and to subscribe towards a fund to commemorate the life work of a man who is spoken of as "the father of dairy bacteriology". Contributions towards the Memorial Fund should be sent to the Director, National Institute for Research in Dairying, Shinfield, Reading.

Bicentenary of the Birth of John Dalton

THE bicentenary of the birth of John Dalton falls in September 1966, and to mark the occasion a programme of events will be held in Manchester, where Dalton lived and worked for most of his life. The celebrations are being sponsored by the Royal Society, the Manchester Literary and Philosophical Society, the Chemical Society, the Royal Institute of Chemistry and the Society of Chemical Industry, with the collaboration of the British Society for the History of Science and the Director of the Science Museum. The detailed arrangements are being made by the Manchester Literary and Philosophical Society. Although the details are not yet fixed, the celebrations will probably be held during the third week in September 1966, and are likely to consist of a specialist conference for the historians of science, followed by a series of meetings of more general interest. The programme will include an exhibition and a number of social events.

Science and the Policies of Governments

Science and the Policies of Governments presents the report of the *ad hoc* Advisory Group on Science Policy of the Organization for Economic Co-operation and Development (Pp. 55. Paris: Organization for Economic Co-operation and Development, 1963). The Group was appointed in 1961 by the Secretary-General to advise him on policy issues of science and technology that are increasingly demanding attention from Governments and the scientific community, as well as on the general orientation and long-term objectives of the Organization in this field. The Advisory Group, of which M. Pierre Piganiol was chairman and Sir Willis Jackson a member, after reviewing generally the new dimensions of science and technology, the public stake in science and the relation of science to economic growth and objectives, points out that science policy is not an abstract concept but of the same nature as economic policy or foreign policy. There has developed on Governments a major and continuing responsibility to make choices about the issues that involve science. The second part of the report discusses science and national policy, including its bearing on scientific policy and on other factors that enter into the effective management and pursuit of scientific work and scientific communication, as well as some of the implications of science in making economic or foreign policy or its bearing on manpower and educational policy. This section of the report insists on the need to formulate a national policy for science, to co-ordinate the various scientific activities of a country, and to integrate science with general policy, and advocates the constitution for these purposes of a Science and Policy Office, the specific functions of which are detailed. From this, in the third part of the report, the Group proceeds to a discussion of international affairs, emphasizing first the need for policy and recommending specifically for the Organization for Economic Co-operation and Development a meeting of Ministers for Science. The agenda visualized would be concerned with national science policy, the concept of which should be clarified, with international scientific co-operation, and with science, economic growth and the role of the Organization for Economic Co-operation and Development. [Such a meeting was, in fact, held in Paris during October 3–4, when the report was considered.]

London and Home Counties Regional Advisory Council for Technological Education

THE fourteenth annual report of the London and Home Counties Regional Advisory Council for Technological Education, covering the period from September 1, 1961, to December 31, 1962, claims that the Council is a vital link in the chain of communication and partnership between education and industry (Pp. 39. London: London and Home Counties Regional Advisory Council for Technological Education, 1963). The Council has been intimately connected with many developing features of technical and technological education, and a working party, sponsored by the Council and the Institute of Education, University of London, has just completed a report on educational research into technical education. Concern is expressed as to the effect on the constitution and functions of the Council of the Government proposals for the reorganization of local government in Greater London. Some 289 courses were supported during the year, 51 being in applied science and mathematics, 98 in engineering and 140 in other subjects. Twelve colleges in the region have been recommended for designation as regional colleges, with a reserve list of three others for future designation. Reports from the Regional Academic Board, the Distribution of Courses Committee and the fifteen Regional Advisory Committees are included.

Centralization and Documentation

A FINAL report to the National Science Foundation made by Arthur D. Little, Inc., on *Centralization and Documentation*, dated July 1963, does not support the large-scale centralization of facilities for storing and retrieval of scientific documents at the present time (Pp. iv+70. Cambridge, Mass.: Arthur D. Little, Inc., 1963). It is considered that a large centralized facility drawing on present-day techniques for retrieving documents is unlikely to achieve the main objective of providing an effective exhaustive capacity for searching the literature to supplement efforts to prevent duplication of research or development. The report recommends, however, a comprehensive programme to indicate the real needs of scientists and engineers for information. Such a survey, conducted with imagination and insight, is an essential pre-requisite to the support of any centralized searching facilities in future, if such facilities are to serve useful functions. Before extensive efforts are made to develop such aids as elaborate word thesauri for existing retrieval systems, the report recommends also the further investigation of the use of statistical techniques for the automatic generation of thesaurus lists and for the automation of some functions at present performed by human intermediaries. To this end, the report suggests that one of the existing medium-sized co-ordinate retrieval systems should be operated experimentally on a statistical association basis Although a body of theory for the design of such systems has been developed and tested successfully on a small scale, there are many practical technical problems to be solved before a useful system incorporating these concepts can be developed Existing co-ordinate searching systems do not possess three necessary characteristics a capacity for generalizing a user's request to make it more compatible with the vocabulary of the retrieval system, a capacity to match automatically the user's depth of search requirement to system parameters, by ranking the documents presented to users in decreasing order of probable relevance, a potential capacity of almost instantaneous reaction between user and searching machine, without need for a human intermediary

The Eastern European Academies of Sciences

PUBLICATION 1090 of the National Academy of Sciences–National Research Council, *The Eastern European Academies of Sciences a Directory*, represents a first attempt by the Office of the Foreign Secretary of the Academy to compile information on academies and research councils throughout the world (Pp v+148 Washington, D C National Academy of Sciences–National Research Council, 1963 2 dollars) The academies of sciences described are those of Bulgaria, Czechoslovakia, Hungary, Poland, Rumania and Yugoslavia The academies of sciences of the U S S R are not included since they have been the subject of other studies, the results of which are already available in the United States The *Directory* presents a brief history of each academy, its present organization, responsibilities, and the titles of its main periodicals Rosters of leading academy officials and of affiliated institutes and their directors are also included, along with biographical sketches of prominent academicians in each country It is claimed that the survey reflects, as accurately as possible, the status of the academies and their principal personnel and programmes in December 1962 As a 'directory' the information supplied is not extensive, and does not supplant that available from, for example, *The World of Learning*, especially as the latter gives full lists of academicians and far more titles of periodicals Thus the use of the present publication will be as a reference guide to the policies and personalities of academies in eastern Europe

Perkin Centenary Awards

APPLICATIONS for the awards of the Perkin Centenary scholarships are invited by the Trustees Each award, tenable for one or two years and renewable for a further year at the discretion of the Trustees, is offered to candidates employed in an industrial firm or other institution concerned with the manufacture or the application of colouring matters to study at a university or technical college Two types of award are available, some to the value of £100, to be used in conjunction with a local education authority grant, and others to the value of £350, which may be increased to £400 for a student living away from home Perkin Travel Grants are also available However, the Perkin Centenary Fellowship will not be awarded in the year 1964–65 Further information can be obtained from the Secretary, Perkin Centenary Trust, c/o the Chemical Society, Burlington House, London, W 1

Does Instrumentation Pay?

FOLLOWING the success of its symposium last year, when more than 100 applicants had to be turned down because of lack of space, the South Yorkshire section of the Society of Instrument Technology is organizing another one-day event in Sheffield on October 24 The theme of this year's symposium is "Instrumentation and Control—Does it Pay?" Intended as the South Yorkshire section's contribution to National Productivity Year, the Memorial Hall of Sheffield City Hall has been booked in anticipation of a large attendance Nine speakers will talk on various aspects of instrumentation and control, drawing extensively from their own practical experience Special emphasis will be directed towards the needs of the smaller firm, where lack of knowledge tends to restrict the opportunities for the application of relatively inexpensive control systems Speakers will include R Barber (Land Pyrometers Ltd, and chairman of the South Yorkshire Section of the Society of Instrument Technology), M A Thomas (Steel, Peech and Tozer), B O Smith (Honeywell Controls Ltd), Dr P Bacon (Guest Keen Iron and Steel Co Ltd), H B Western (National Industrial Fuel Efficiency Service), J Hancock (Unbrako Steel Co Ltd) A Barker and R F Wright (Thos Firth and John Brown Ltd), I C Ross (Steel, Peech and Tozer) The symposium will conclude with an open forum under the chairmanship of Mr Barber Further information can be obtained from C G Hague, A C E-Hartons Ltd, 109, Rockingham Lane, Sheffield, 1 An attendance fee of one guinea is being charged for the meeting

Announcements

THE twenty-first annual Pittsburgh Diffraction Conference will be held at the Mellon Institute, Pittsburgh Pennsylvania, during November 6–8 Further information can be obtained from W M Biagas, Crucible Steel Company, P O Box No 7257, Pittsburgh 13, Pennsylvania

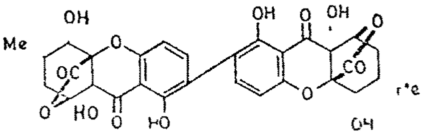
A SYMPOSIUM on "The Toxicology of Cosmetic Materials" will be held at the Town Hall, Leamington Spa, during November 19–20, by the Society of Cosmetic Chemists of Great Britain Registration forms together with full details can be obtained from the general secretary Mrs E Millman, 2 Lovers Walk, London, N 3

THREE short courses are being organized by Bradford Institute of Technology during November on "Developments in Polymerization" (November 8–9), "Recent Industrial Applications of X-ray and Electron Diffraction" (November 14–15), and "New Techniques in the Study of Materials" (November 22–23) Further information and application forms can be obtained from the Registrar, Bradford Institute of Technology, Bradford 7

A SERIES of courses of special lectures in higher technology will be held at Woolwich Polytechnic during the academic year 1963–64 These will include courses in mathematics, physics and telecommunications, chemistry, biology, civil, mechanical and production engineering, electrical engineering, economics and management Further information can be obtained from the Secretary, Woolwich Polytechnic, Woolwich, London, S E 18

THE ninth annual conference on "Magnetism and Magnetic Materials", sponsored by the American Institute of Physics and the Institute of Electrical and Electronics Engineers, will be held in Atlantic City during November 12–15 In addition to the usual topics the Committee is encouraging papers relating to superconductivity and magnetism Further information can be obtained from Mr William D Doyle, Franklin Institute Laboratories, Philadelphia 3, Pennsylvania

ERRATUM There is an omission of two OH groups from the formula of ergoflavin given in the summary of Prof J Monteath Robertson's presidential address to Section B (Chemistry) at the Aberdeen meeting of the British Association for the Advancement of Science, which appears on p 883 of the August 31 issue of *Nature* The formula should be



INDUSTRIAL AND AGRICULTURAL RESEARCH IN BELGIUM

THE annual report of the Belgian Institute for the Encouragement of Scientific Research in Industry and Agriculture for 1962* records the award during the year of 62 subsidies totalling 303 million francs, on which 319 research workers and 930 technicians were engaged Of this total, 65 million francs went to the National Centre for Metallurgical Research for work in physical and chemical metallurgy, on constructional steel and special steels and the metallurgy of iron, etc Eight grants, totalling some 20 4 million francs, also went to the Centre for Scientific and Technical Research on the manufacture of metals The Committee for Mapping the Soil and Vegetation of Belgium received a subsidy of 23 5 million francs, and the Committee for the Study of the Diseases and Nourishment of Cattle 16 7 million francs, while another 16 million francs went to the Centre for Applied Electronics for investigations on impulsion circuits, industrial control systems and of amplifiers, modulators and oscillators for transistors The Road Research Centre received a subsidy of 14 75 million francs, while the Scientific and Technical Centre of the Belgian Textile Industry was granted 11 5 million francs for research covering cotton, wool jute, linen, rayon and acrylic fibres Apart from a subsidy of 11 35 million francs to the Centre for Scientific and Technical Research of the Metal Manufacturing Industry included among the eight already noted, and one of 10 75 million francs to the Belgian Society for Nitrogen and Chemical Products of Marly, only the subsidies of 9 9 million francs to the National Committee for the Study of Fruit Cultivation and of 9 5 million francs to the Committee for the Study of the Solid State are worthy of special mention The Committee for the Scientific and Technical Study of Milk received 5 8 million francs, the Committee for the Study of High Polymers 5 6 million francs for research on the behaviour of high polymers to irradiation on the degradation of high polymers used as insulators, and on photopolymerization, the Research Centre for Animal Breeding and Fodder in High Belgium 5 27 million francs, and the Scientific and Technical Research Centre for the Explosives Industry 5 25 million francs

The only other grant of 5 million francs or more was to the National Centre for Herbage and Fodder Research but 4 7 million francs went to the Belgian Institute for Improvement of Beetroot, 4 3 million francs to the Belgian Centre for the Study and Documentation of Water, for research including, besides investigations on potable and industrial waters, on corrosion and effluents, some work on atmospheric pollution, and 4 million francs to the Committee for the Study of the Structure of the Soil Among other large subsidies may be mentioned 3 8 million francs to the Technical and Scientific Centre for the Brewing, Malt and Related Industries, 3 4 million francs for tobacco research, 3 4 million francs for investigations of vegetable reproduction, 3 1 million francs for work on the conservation of fruit and vegetables, and 3 1 million francs for research on vegetable parasitology, 2 2 million francs went to the Belgian Wood Centre and almost 2 million francs each to the Belgian Centre for the Study of Medicinal Plants, the Research Centre of the Belgian Ceramic Industry and the Committee for the Study of Agriculture Grants totalling almost 3 million francs went to the National Centre for Scientific and Technical Research for the Cement Industry, of which some 1 3 million francs were jointly for the Scientific and Technical Centre for Construction for an investigation on the measurement of the resistance of bitumen to compression The report indicates briefly the extent of the investigations for which the subsidies are given and includes a list of publications during the year dealing with the subsidized investigations

* Institut pour l'Encouragement de la Recherche Scientifique dans l'Industrie et l'Agriculture, Bruxelles Rapport Annuel, Exercice 1962 Pp 277 (Bruxelles Institut pour l'Encouragement de la Recherche Scientifique dans l'Industrie et l'Agriculture, 1963)

CIVIL RESEARCH POLICY

THE report of the F B I (Federation of British Industries) Working Party on Civil Research Policy* is the outcome of a remit from the Federation to consider recommendations as to how the Government should support civil scientific research and development in industry, bearing in mind the possible lessening of such support for defence research and development, which has had valuable civil application Part of the memorandum is addressed to industry and part to the Government

The prime concept of the report is the presentation of a case intended to find ways and means of increasing very substantially the financial resources to be put into civil research and development The magnitude of the target is a sum of £100 million per annum A considerable proportion of this, it is advised, should be spent as direct support of research and development in industry The responsibility for determining the allocation of such funds to the many claimants is recommended to be assigned to the Minister for Science, advised by a Council having presumably wide representation

The following comments on the report in question are based on a long experience in three distinct fields of scientific research in industry with a company noted for its technological development; in the university, in charge of a technological department; and in research associations, covering no less than seven in various capacities from member of research committees to Department of Scientific and Industrial Research visitor

A very important statement of the Working Party amounting almost to a reservation, is its expression of concern as to whether its ideas would be practicable in terms of man-power This question, apart from the problem of finding the money, becomes the crucial one of the whole matter Mere multiplication of numbers will not give a corresponding increase of achievement in respect of fruitful research though it may give acceleration of the rate of progress at possibly a relatively increased price Rather should the means be sought of strengthening existing organizations This is in some measure advocated in the report, but it is not suggested to apply in any marked degree to the industrial Research Associations Indeed as a broad generalization the Working Party says "We are bound to confess that the opinion in industry about Research Associations is not universally favourable" But how could one in all seriousness expect a unanimous opinion from industry on so wide a matter? I suggest that on balance industry is favourably impressed by the system of Government-aided research associations and by their achievements although it no doubt feels, as the report suggests, that methods of financing may need recasting and particularly that the measure of Government financial support is inadequate It is true that in the past there has been a serious lack of means in Britain to put to their fullest use the results of research For their part, the research associations have not had in general the means to pursue active development in this respect This function has been regarded as the responsibility of industry, but it becomes increasingly clear that the large-scale development of important research results must in the future become the responsibility of the scientist, the technologist, industry and Government, each playing an appropriate part

---

* *Civil Research Policy a Report of an F B I Working Party* Pp iii+11 (London Federation of British Industries, 1963) 2*s* 6*d*

The research associations have in this connexion an important potentiality which a number of them have developed very successfuly, namely, the practicability of close collaboration between the technical elements of industry and the scientific staffs of the associations The technical staffs of industry become closely associated with the progress of the work of projects in which they are interested There can be developed active collaboration by many avenues; co-operation of member firms in joint researches, conferences, joint committees and frequent contacts between the technical staff of the works and the research station The intelligence service of the research association alone is a powerful instrument in developing the growth of that research-mindedness which, as the report says, "cannot be achieved until all heads of companies become fully research minded nor until adequate status is accorded to those responsible for research and development in the business" This is done successfully in some industries in Britain and more often in some countries abroad, notably France On the other hand, the scientist should not expect the advocacy of his case to be undertaken by his lay brethren The attitude to be adopted should be that a worthy cause deserves support

Noteworthy is the point in this respect that the many achievements of the research associations have been made with only a small fraction of the public support that the Working Party now suggests as being necessary

In the scheme advocated there could be new problems arising from lack of co-ordination, particularly in the privately inspired research and development contract, while at the same time there could arise a danger of over-rationalization by centralization of civil work at fewer centres The secret of successful research I believe to be freedom from external interference of the skilled team, for team it must be to-day in much applied research The largest organizations inevitably become unwieldy in administration To be able to remain successful they have to resort ultimately to decentralization There is a point of balance between the extremes of insufficient and over-control, which may become a critical issue

It should of course be realized that the elements of progress are at work all the time Often the most important are those about which there is least publicity It is to be hoped that those who are called on to operate the 'priming-pump' may have the wisdom to guide the stream rightly

R J SARJANT

THE MELLON INSTITUTE, PITTSBURGH

THE fiftieth annual report of the Mellon Institute*, covering the year ended February 28, 1963, includes a historical sketch of the development of the Institute written by Dr E R Weidlein

Dr Weidlein traces the growth of the Institute and of the industrial fellowship established by Dr R K Duncan at the University of Kansas in 1907, and the Department of Industrial Research he established at the University of Pittsburgh in 1911 with the support of A W and R B Mellon The Mellon Institute of Industrial Research and School of Special Industries was first established in 1913 as a part of the University of Pittsburgh, becoming independent as the Mellon Institute of Industrial Research (shortened to Mellon Institute in 1962) in 1927, although it still maintains close co-operation with the University Functionally a centre for pure and applied research, it is also a clearing house for advanced scientists and a clearing house on specific scientific information At the end of the year, out of a total personnel of 573, 118 held Ph D s or other doctorates, 33 were M Sc s and 303 were employed in scientific activities, while in addition 49 specialized technicians and craftsmen were mainly concerned with servicing research projects Operating expenditure on independent and sponsored research amounted to 6 2 million dollars, and 600,000 dollars were also spent on improvement of existing or purchase of new equipment

In biochemistry, investigations of acid-fast bacteria established that *p*-aminobenzyl alcohol is hydroxylated to *p*-aminophenol, and a new pathway for the metabolism of *p*-aminobenzoic acid has been established chemically by the use of radioactive isotopes The carboxypeptidase *N* of human plasma fraction IV–I that activates the hypotensive peptides, bradykinin and kallidin, have been further investigated, and a mica replica technique used to examine macromolecules and various polymers of myosin in the electron microscope In organic chemistry the rotational isomerism of some mono- and di-substituted propenes has been investigated by nuclear magnetic resonance spectroscopy, *cis, cis, cis*-1 4 1-*cyclo*nonatriene synthesized from indane in seven steps and also the pseudo-aromatic hydrocarbon, hexaphenylpentalene, and dioxocyanogen, the first difunctional nitriloxide A multi-state mechanism has been proposed for homogeneous ionic polymerization, studies of the statistical thermodynamics of dilute polymer solutions continued in an examination of the equation of state for solutions of branched polymers, and the light-scattering behaviour of dilute solutions of macromolecules was studied as a function of temperature with a precision photometer having close temperature control, high angular resolution and signal stability In geochemistry, investigation of the origin of stony meteorites was a major project, and in inorganic chemistry the study of the geometric isomerism of the diphenylalkylphosphine complexes of nickel halides continued, new routes to compounds containing four-membered heterocyclic rings of the type metal  metal were discovered for nickel, cobalt, iron, manganese and molybdenum, and a unique chemical system capable of carrying molecular oxygen or hydrogen

In physical chemistry, investigations of the scattering of electrons by molecular gases were initiated and experiments on the vibrational spectra of various compounds completed, while the structures of tetraphenylsilicon and tetraphenyltin were refined by full-matrix 'least-squares' technique using anisotropic temperature parameters for all atoms In radiation chemistry, investigations of the reaction kinetics of halogenated radicals have been extended to the examination of the relative rates of combination and disproportionation of trichloromethyl radicals with various other radicals In continued investigations of the normal stress effect, the concentration-dependence of solutions of polyisobutylene in cetane has been studied in steady-study torsional shearing between two parallel circular disks and between a cone and a disk Work continued on the development of new methods for obtaining accurate solutions of the molecular Schrodinger equation, and in metal physics tensile deformation investigations were carried out of the close-packed hexagonal copper-germanium phase, while the deformation stacking fault probability was measured in dilute intranoble metal alloys containing up to 5 atomic per cent solute A list of publications is included

WHEAT GENETICS

THE second International Wheat Genetics Symposium was held during August 19–24 at the University of Lund, Sweden The meetings produced a broad survey of many recent advances in knowledge of the genetical architecture of the hexaploid wheat of commerce, *Triticum aestivum*, and of some of its relatives in the genera *Triticum*, *Aegilops*, *Agropyron* and *Secale* Naturally, considerable attention was directed to ways in which the new information could be exploited in the improvement of the crop, but since wheat offers many unique opportunities for genetical work there was no restriction to topics of immediate practical importance

For example, R C F. Macer (Great Britain), R G Anderson (Canada), D R Knott (Canada) and A T. Pugsley (Australia) considered the genetic control of resistance to stripe rust, leaf rust, stem rust and powdery mildew respectively In the main, similar patterns of major gene effects are responsible for differences in resistance to all four fungal pathogens, and, as was pointed out by W Q. Loegering (United States), alleles for resistance or susceptibility in the host could be matched by alleles for avirulence or virulence in the fungus, provided the latter had a sexual stage Basic information of this type has a direct practical value since the recognition of the mode of inheritance greatly facilitates the use of genetically determined resistances in breeding programmes Moreover, in all these instances the genes for resistance are being isolated, in otherwise equivalent genetic backgrounds giving full susceptibility, so that differential hosts will be available that will permit accurate assessments of the virulence genotypes of pathogens isolated in the field

The practical importance of incorporating, in wheat, the genetically determined disease resistance of other species was widely accepted during the Symposium The isolation against the wheat background was reported of single chromosomes from *Agropyron* giving resistance to stripe, stem and leaf rust by A Wienhues (Germany), Y Cauderon (France) and D. R Knott (Canada), and of one giving resistance to the wheat streak mosaic virus by E E Sebesta (United States) R C F Macer (Great Britain) and C J Driscoll (Australia) reported that single chromosomes of *Secale*, isolated against a wheat background, would give resistance to stripe rust and leaf rust In several instances, use was being made of translocations induced by irradiation to transfer to a wheat chromosome the critical segment of the alien chromosome giving disease resistance

A remarkable piece of engineering of this type was described by D R Knott (Canada) It involved the transfer of *Sr*6, a gene giving stem rust resistance carried on chromosome 2*D* of the *D* genome of *T aestivum*, to *T durum*, a tetraploid in which chromosome 2*D* has no homologue Chromosome 2*D* was isolated, by backcrossing, against the *T durum* background and a satisfactory translocation of *Sr*6 to a chromosome of *T durum* was induced and made homozygous Not only is a new form of resistance now available at the tetraploid level, but also the *Sr*6-carrying tetraploid can be crossed to *T aestivum* and the gene, in its new position, back-crossed into the hexaploid, and so obtained in four doses Whether duplication of the gene will show a dose effect that improves disease resistance remains to be seen A possible alternative to the introduction of alien variation by translocation might be to substitute a pair of alien chromosomes for a pair of wheat chromosomes This can be achieved by sequences of hybridizations between various aneuploid lines A Wienhues (Germany) described the substitution of *Agropyron* pairs for wheat pairs, and B C Jenkins (Canada) the substitution of *Secale* pairs for wheat pairs There was some discussion as to whether an alien pair could only be expected to replace a homoeologous wheat pair with which it had a common evolutionary origin, but insufficient evidence is as yet available to clarify the issue

H Kihara (Japan) described the production of male sterile forms of wheat by the substitution, by backcrossing, of the wheat nucleus into the cytoplasm of various other species, while J. W. Schmidt and V A Johnson (United States) outlined the discovery and use of genes that restore male fertility This work clearly indicates that the commercial exploitation of hybrid wheat may soon be possible It is not yet known whether there will be sufficient hybrid vigour to produce an increase in yield adequate to cover the increased cost of seed production—an increase in yield of about 20 per cent is estimated to be necessary Moreover, many hold that genotypes giving the greater yields should be fixable by selection in the derivatives of hybrids showing heterosis, although this ignores the probable difficulties of breaking some repulsion linkages in a few generations of recombination

The accumulation of conventional linkage data has been very slow in *T aestivum*, but E R Sears (United States) demonstrated how this could be remedied by using telocentric chromosomes to estimate linkage distances between single major genes and the centromere In this way some linkage information has already been obtained about chromosomes 3*B* and 6*B* Although aneuploidy has been of the utmost value in the genetic analysis of *T aestivum*, as was demonstrated by R I Larson (Canada) and J Kuspira (Canada), it has been less useful with the tetraploid wheats—presumably because they have fewer duplicate loci and are consequently intolerant of aneuploidy However, M Noronha-Wagner and T Mello-Sampayo (Portugal), working with *T durum* (a tetraploid), have been able to hold the nullisomic or monosomic condition for some chromosomes provided that there was compensation for the deficiency by extra dosage of the homoeologue in the other genome Of interest was the fact that there is some tendency for homoeologous chromosomes to pair at meiosis when in the monosomic–trisomic condition, despite the normally diploid-like meiotic behaviour of the tetraploid wheats

R Riley (Great Britain) provided confirmation of the hypothesis that homoeologous meiotic pairing and recombination occur when the restricted pairing specificity, imposed by the activity of chromosome 5*B*, is relaxed Moreover, the relaxation of specificity permitted the incorporation in wheat chromosomes, by recombination, of segments from the chromosomes of other species in a manner that was otherwise impossible In a parallel investigation of the same system, M Okamoto (Japan) had selected induced mutants that altered the activity of chromosome 5*B* in the regulation of meiosis He indicated the likelihood that such mutants could be stabilized in stocks that would have considerable potential value in practical breeding work

C F Konzak (United States) and R E Scossiroli (Italy) considered the value of induced mutations in wheat breeding and both emphasized the particular value of changes that affect quantitative characters. The genetic analysis of the protein quality of the grain was discussed in relation both to the physical causes of the different properties of flours and of their assessment in small-scale tests Finally, no ultimate verdict was possible by J Mac Key (Sweden) or M. S. Swaminatham (India) on the true nature of the genes on the pronounced effects of which are erected many taxonomic categories in *Triticum.*

Wheat is, with rice, the principal food crop of the world and to a considerable degree its present pre-eminence is owed to its extreme genetic versatility. The second International Wheat Genetics Symposium marked a further advance in our comprehension of this versatility and confirmed that the cytogenetic structure of *T. aestivum* continues to be the subject of intensive investigation in many parts of the world. Indeed there were several workers from the U S S R. present, all of whom treated the genetics of wheat from the Lysenkoist point of view. That some of the fundamental cytogenetic investigations of the past have already been turned to practical account is gratifying, and promises well for the future of the more thorough understanding that we are now attaining.

RALPH RILEY

TEACHING OF BIOLOGY

By DR GARTH UNDERWOOD
University of the West Indies, Trinidad

THERE has been considerable recent discussion of the effect on the teaching of biology of the growing field in which the traditional distinction between botany and zoology is disappearing Catcheside[1] and Darlington[2] put forward proposals for teaching the biological sciences which bring together microbes, plants, animals and man Their proposals, however, still retain the divisions of biology into such aspects or "disciplines" as genetics, ecology, taxonomy and physiology

These several biological disciplines grew up separately at a time when there was no general body of biological theory to relate them to one another They started as inductive sciences Investigators at this stage were trying to ask the right questions and to devise techniques to obtain the answers Discussion of techniques figured largely in the discussion of the results and theories were fragmentary and controversial The attention of each investigator was understandably turned in on his own field, at this stage other fields had little to offer him. This was the period during which there developed a deep gulf between field and laboratory This period also produced some biologists who now look rather strange the biochemist to whom a rat was the animal reared in the room at the end of the corridor, the taxonomer in a dusty museum whose study was, as Philip Gosse pointed out a hundred years ago, not so much biology as necrology, the geneticist who had no idea where to start looking for a *Drosophila* in the field, the physiologist who did not know the systematic relationships of (or sometimes even how to identify) the organisms which he studied Parenthetically it may be remarked that this is perhaps why the origin of new adaptive features remains an obscure problem[3] An account of the origin of a new feature would require a knowledge of its structure and function, of its genetical and developmental determination and of the habits and ecology of the organism; in other words, a synthesis of the disciplines which have usually been studied separately.

I would like to offer some suggestions aimed at achieving a greater merging of these several aspects of biology as well as a merging of plant and animal studies We are still far from being able to proceed in a series of deductive steps from simple molecules to twentieth-century human society, however, we can now suggest the lines along which large areas of biology may be linked together Organisms have been most studied as individuals Bacteria, protists and higher plants and animals represent three grades of individual organization Genetics has an important contribution to make to the discussion of cellular structure and function and, in the case of the higher organisms, to the organization of the development of the individual Consideration of the higher organisms leads to the structural and physiological differentiation of tissues and organs Some topics such as animal behaviour and locomotion remain frankly zoological Such relationships as that between insect and flower, host and parasite, mimic and model or between the bees in a hive can be looked on as special cases of relationship between individuals

Studied as individuals organisms can, however, be understood only in part This leads us to the study of populations A consideration of populations involves such topics as population dynamics, territory, living space, overt and concealed polymorphism, natural selection, geographic variation, reproductive isolation and the nature of species The rules for dealing with lower taxonomic categories follow quite naturally on discussion of species A number of special relationships already examined at the individual level may now be studied at the population level, insect and flower, host and parasite, mimic and model are viewed from a different angle

From the relatively simple relationships between populations just mentioned we can proceed logically to the complexity of major communities Here a number of ecological ideas such as niche, trophic-level and pyramid of numbers can be introduced The grades of individual organization and the metabolism of plants and animals, already examined, now take on a new significance in the new context From the examination of community structure we may proceed to a review of the adaptive diversity of plants and animals, a review of the niches which are actually filled

Living organisms will now have been investigated as individuals, in populations and as members of communities It remains for the student to recognize that recent living organisms have a long evolutionary history behind them that the present cannot be fully understood without reference to the past This leads us to consider temporal changes in the physical environment, the fossil record and the evidence on which phylogenetic schemes are constructed, here morphology has a major place and biogeography and the comparative approach to physiology, biochemistry and cytology can be considered To present the findings of phylogenetic studies, rules for the treatment of higher taxa are necessary. The actual results of phylogenetic studies can now be reviewed in outline in the form of a historical survey of plants and animals and a classification of recent organisms

Man will have furnished good illustrative material for some of the earlier parts of the course such as the nature of gene action, natural selection and population dynamics An important part of the general educational value of a biology course, however, lies in the light which it throws on man himself Such a course could well conclude by taking a look at man in the light of biological knowledge the origin of man, genetics and physical anthropology, the domestication of plants and animals, population studies, food supplies, disease, radiation hazards and, finally, man in space

The conventional 'packaging' of biological teaching made it easier for the student to leave out important aspects genetics because he had trouble with ratios, physiology because his experiments never seemed to work, ecology because the lectures of Dr *X* were dull A greater merging of these branches of biology will help to create an atmosphere in which ecology or genetics could no more be left out than the cell theory or water and carbon dioxide The greater maturity of the branches of biology means that the presentation of conclusions of general significance is less dependent on an explanation of techniques, there is therefore less chance that a student will fail to appreciate important conclusions because of his difficulties with the way in which the conclusions were reached Biology can thus be presented as a subject which has matured to the point that every branch has some bearing on every other branch, the student can be brought up to feel that the physiologist who knows nothing of genetics, the taxonomer who is unacquainted with the science of ecology and the biochemist who is ignorant of evolutionary theory are biologically uneducated

3 : 5-DIHALOGENO-4-HYDROXYBENZONITRILES AS HERBICIDES

3 : 5-Dihalogeno-4-hydroxybenzonitriles : New Herbicides with Molluscicidal Activity

2 4-DINITRO-6-METHYLPHENOL (DNC) is a herbicide with high contact phytotoxicity which has been used in agriculture for many years, especially for the destruction of broad-leaved weeds in cereal crops The activity of this molecule is specifically related to the presence of $-NO_2$ groups in the 2- and 4-positions to the –OH group though the 6-methyl grouping can be replaced by hydrogen or certain other alkyl groups without appreciable loss of phytotoxicity

I have investigated the capacity of DNC and other aromatic nitro compounds to form intermolecular complexes with amines and hydrocarbons[1,2] In the first of these investigations[1] it was established that the $-NO_2$ groups in 1 3 5-trinitrobenzene can be replaced by –CN without destroying the capacity to form molecular compounds, though the effect of the $-NO_2$ group in promoting compound formation was found to be greater than that of –CN It was concluded from this work that the inductive effects exerted by these groupings in the benzene ring are similar in magnitude

Such considerations led me to make a systematic investigation of the effects on herbicidal action of replacing the $-NO_2$ groups in DNC by –CN A number of derivatives of 2- and 4-hydroxybenzonitrile were therefore synthesized and their activity as weed-killers was assessed by standard methods In general, poor performance only was shown by derivatives of salicylnitrile, but a number of compounds derived from 4-hydroxybenzonitrile were shown to possess outstanding herbicidal activity The most promising of these, first tested in June 1959, was 3 5-diiodo-4-hydroxybenzonitrile (later referred to as ioxynil)

The 3 5-dibromo analogue (broxynil) also showed high activity but the corresponding dichloro-derivative was much less active The water-soluble sodium, potassium and ammonium salts of ioxynil and broxynil and certain of their esters were prepared during 1959–60 and tested against a range of crop and weed species It was soon established that they are capable of destroying the tissues of many plants when applied as a spray at concentrations as low as 250 p p m The effect is entirely that of a contact herbicide and no systemic activity has been observed The compounds become inactivated by contact with soil Against most plant species the phytotoxicities of ioxynil and broxynil are considerably greater than that of DNC, but, as with this compound, the differential wetting concept enables them both to be successfully used for destroying broad-leaved weeds in certain monocotyledonous crops Ioxynil was tested for me by P H Rosher in Trinidad against a range of tropical crop and weed plants in December 1959 Most species were seriously affected or killed by a spray containing 1,000 p p m , grasses, millet and maize showing the least damage Since that time a number of trials have been carried out by P Cozens, Miss L MacDonald and D H Bartlett at this College both with ioxynil and broxynil The former has always proved to be the more effective compound In two trials designed to examine their capacity for the destruction of potato haulm, both substances gave excellent results

Investigations of the mode of action of these compounds are being carried out by my colleagues and me and it has now been established by M Kerr that the substances are strongly active in uncoupling oxidative phosphorylation within plant tissues Since this property is shown also by DNC and by pentachlorophenol, both of which are good molluscicides, steps were taken to examine ioxynil and broxynil for their capacity to kill snails This work was carried out for me by J Duncan, of the Tropical Products Research Unit, Department of Technical Co-operation, who has consistently shown ioxynil to have an LC_{50} of about 0 5 p p m and broxynil about 2 p p m when tested as their sodium salts against *Australorbis glabratus*, a snail host of *Schistosoma mansoni*, the causative agent of intestinal bilharzia Against another species, *Biomphalaria sudanica*, also a snail host of *S mansoni*, the LC_{50} was $<$ 1 0 p p m for ioxynil and $<$ 3 0 p p m for broxynil Ioxynil has also been shown in immersion tests to be some ten times more effective than metaldehyde against several mollusc species by I F Henderson and P F Newell at Rothamsted Experimental Station The compound, however, has no attractant properties A small-scale test of ioxynil for controlling water hyacinth (*Eichhornia crassipes*) has been carried out in Egypt with promising results The destruction of this weed, which impedes water movement in the irrigation canals, is an urgent problem, and supplies of the compound have been sent to Egypt for further trials to be undertaken The possibility of destroying water hyacinth and controlling the vector of bilharzia simultaneously with ioxynil would appear to warrant investigation

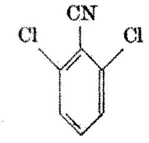
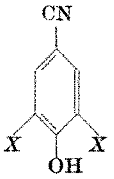
Herbicidal Action of 3 : 5-Dihalogeno-4-hydroxybenzonitriles

THE isolation of the plant growth regulator indolyl-3-acetonitrile from cabbages by Henbest *et al* [1] in 1952 directed some attention on the role of the nitrile group, more particularly when it was later shown by a number of workers that this molecule was active *per se* and that activity was not solely dependent on the conversion of the nitrile into the carboxylic acid Since then several herbicidally active nitriles have been described, for example, diphenylacetonitrile[2], triazine nitriles[3], and more particularly 2 6-dichlorbenzonitrile[4] (I) It seems clear that there is no rational or predictable relationship between the spectrum of herbicidal activity (if any) of the aromatic nitriles and the corresponding carboxylic acids. Nor indeed has any clear pattern of structure-activity relationship yet emerged in this class. This topic has recently been reviewed by Barnsley and Yates[5].

A considerable number of nitriles was accessible in our laboratories as a result of earlier chemotherapeutic work on amidines, and a search for useful herbicidal activity among these was, therefore, attractive experimentally, albeit empirically. One outcome of this work has been to uncover a high level of activity in 3 : 5-dihalogeno-4-hydroxybenzonitriles (II).



(I) dichlorbenil



(II)

X = I M and B 8,873
X = Br M and B 10,064
X = Cl M and B 9,895

Although some formal chemical resemblance exists between I and II in that each contains a benzene ring, an aromatic nitrile and two halogen atoms, it seems that the type of herbicidal activity is so different as to imply fundamentally different modes of action. Thus I is active as a pre-emergent herbicide whereas the 4-hydroxy benzonitriles so far examined possess much greater activity when applied as a foliar spray. Moreover, the position of the halogen atoms in relation to the nitrile group which is required for maximum activity is quite different. Thus, if the halogen atoms in I are in the 3 : 5 positions or in II are in the 2 : 6 positions the nitriles are very much less active. That the nitrile group is an important part of the molecule is shown by the twenty-fold diminution of activity of the corresponding 4-hydroxy 3 : 5-dihalogeno benzoic acids.

Field trials of M and B 8,873 and M and B 10,064 as a foliage spray are in progress on cereals and some leguminous crops. The results so far available confirm the earlier work in the glass-house that most annual weeds, including the 2,4-D-resistant weeds, are controlled at low dose rates.

The details of recommendations for commercial use must await the outcome of the further investigations, now in progress, into practical applications of these compounds in a variety of crop-weed situations. Residue examinations, with the aid of radioactively labelled material, are in hand and the results so far indicate that there is a fairly rapid disappearance of both compounds from treated wheat, oats and barley.

SOIL COMPACTION AND MANGANESE DEFICIENCY

By DR. J. B. PASSIOURA and PROF. G. W. LEEPER
Department of Agricultural Chemistry, University of Melbourne

MANGANESE deficiency disease, best known as the characteristic 'grey-speck' of oats, has long been a scientific puzzle. It occurs characteristically on soils in the *p*H range of 6·5–8·0 (sometimes outside), and characteristically (though not exclusively) on sandy and on peaty soils. Two reasons have been given for the unavailability of manganese to oats and other sensitive plants growing on these soils. Firstly, that practically all the manganese has been biologically oxidized to the higher insoluble oxides (collectively denoted here as MnO_2). Secondly, that the manganese retains its valence of two but is held in such a strong covalent link by organic colloids that the root cannot obtain its necessary supply of an ounce per acre. This second reason does not concern us here, and we have produced much theoretical and experimental evidence against it elsewhere[1].

The first explanation, depending on the insolubility of MnO_2, will not do either. Against it we have the many successes reported in curing 'grey-speck' with finely divided insoluble oxides[2] including the product of microbial oxidation[3]. Sensitive plants growing on neutral and alkaline soils may be healthy at very low contents of exchangeable manganese so long as there is ample MnO_2 extractable with the gentle reducing agent quinol[4]. However, there are still many exceptions to this last relation. Some neutral soils are healthy in spite of a low content of quinol-soluble manganese, and some, especially organic soils, are deficient in spite of a high content. Now organic soils are typically loose and open, and their exceptional behaviour suggests that the availability of manganese may be related to the degree of compaction.

We have compacted two soils on which 'Algerian' oats (a local variety) showed severe 'grey-speck', and have found, both in pots in the greenhouse and in plots in the open, that the disease was mostly cured, with up to a 50-fold increase in grain production. The two soils were: (*a*) the fine sandy loam from Mount Gambier, South Australia, a young soil[5] formed on calcareous basaltic tuff, *p*H 7·4; its bulk density was 0·85 uncompacted, 1·0 compacted: (*b*) the sandy loam of the grounds of the University of Melbourne, an imported soil[6] which has been *in situ* for more than fifty years, *p*H 7·4; bulk density 1·2 uncompacted, 1·5 compacted. Even in its compact state this soil was permeable, and in the plot test on the morning after a rain of 4 cm there was no water lying on its surface.

The pot tests were done either in an unheated glasshouse or under a glass canopy in a bird-proof cage, using 15 cm × 20 cm glazed ceramic pots in duplicate. For compacting, successive lots of 700 g moist soil were added to the pot and given a set number of 2 kg × 10 cm blows with a Proctor hammer, namely 10 for the University soil, and one lot of 15 and one of 25 for the Mount Gambier soil. Water was added to keep the pots to constant weight, using a figure found to equal the percentage of water at *p*F 2·5.

With the University soil in pots, the grain yield of Algerian oats (a sensitive variety) was 0·04 g on loose and 2·3 g on compacted soil; that of Palestine oats (a tolerant variety) was 1·3 g on loose and 9·1 g on compacted soil. On the plots in the open, the general effect of compaction was healthier growth and three weeks advance in heading. Quantitative results are not quoted since germination was damaged by compacting on one of the six square-yard plots.

Two soils from Mount Gambier were used, *C*, with no manganese added at any time, and *M*, coming from the same source, but having been mixed 27 years previously with a synthetic reactive MnO_2 at the rate of 80 p.p.m. of manganese. This residual manganese was almost useless on the loose soil (its initial good effect having disappeared after about ten years), but it was valuable on the

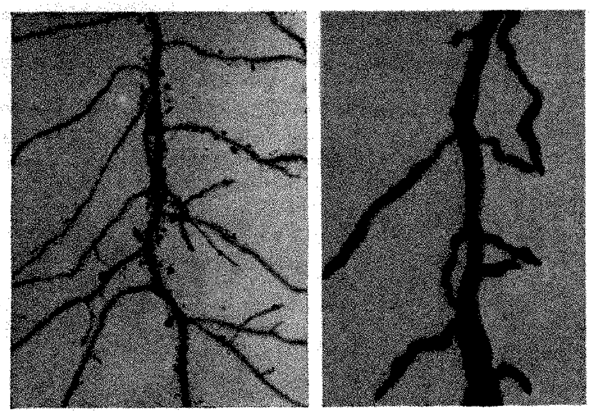

Fig. 1. Roots of Algerian oats growing on University soil. Left, loose soil; right, compact soil (both *c.* × 2)

compact soils. Two degrees of compaction were used, as here. With the greater degree of compaction (*B*) there was much more growth than with the lesser (*A*), both of Algerian on soil *M* and of Palestine on the control soil (Table 1). While the bulk density of *B* was only 4 per cent greater than that of *A*, the resistance to a penetrometer needle was almost twice as great.

Table 1. YIELD OF DRY MATTER (g) OF OATS GROWN ON MOUNT GAMBIER SOIL, WITH AND WITHOUT COMPACTION

Soil	Oat variety	Treatment of soil Loose	Compact *A*	Compact *B*
C	Algerian	0·55	1·05	0·92
C	Palestine	1·87	2·13	4·16
M	Algerian	0·91	2·66	3·57
Bulk density		0·85	0·99	1·03

The distribution of pores in the potted soils of Mount Gambier was measured by pressure-plate (Table 2). The loose and compact soils have much in common, the main difference being in the largest pores of all (drained at 10 cm tension, equivalent to 300μ diameter). The two degrees of compaction give almost identical curves; the difference between these two soils is in their shear strength, not in their aeration. The aeration of both appears from Table 2 to be adequate.

The conventional explanation for thus overcoming the deficiency would be as follows. The more compact soil is supposed to be less freely aerated, so that more carbon dioxide accumulates, so lowering the *p*H of the soil solution; and less oxygen is available for the normal microbial oxidation which converts the mobile manganous ion into MnO_2. This explanation is mistaken. First, the manganous ion extractable with HNaCaEDTA at *p*H 8 after Beckwith[7] was 0·3 p.p.m. on loose and compact alike. Secondly, the *p*H of the soil solution is not lowered sufficiently to account for the effect; when carbon dioxide is circulated through the Mount Gambier soil in amounts such as to reach twice the concentration (0·5 per cent) found in the corresponding compact soil, the plants show no improvement. Thirdly, the diffusion of oxygen in the compact University soil has been measured using a platinum electrode after Lemon and Erickson[8] and is no less than in the loose soil. Fourthly, the bulk density of the Mount Gambier soil after compaction was only 1·0. Further, all such explanations ignore the fact that manganese deficiency is typically a disease of the wetter and cooler climates of the world, where aeration might generally be expected to be less than in the drier and warmer climates.

Table 2. AMOUNTS OF WATER HELD AT VARIOUS TENSIONS BY MOUNT GAMBIER SOIL, LOOSE AND TREATED TO LOWER DEGREE (*A*) AND HIGHER DEGREE (*B*) OF COMPACTION. g WATER PER 100 g DRY SOIL

Tension cm water	Loose	Compacted *A*	*B*
0	70	63	64
10	60·6	57·0	57·4
40	59·4	57·2	57·6
100	41·9	41·4	42·5
340	32·9	31·5	31·7
1,000	29·4	26·8	26·6

A more satisfactory explanation follows from the theory that the reserve of available manganese in a neutral soil consists of reactive MnO_2, which is insoluble in water but capable of rapid dissolution by mild reducing agents such as neutral quinol[4]. We suggest that the root itself acts by a 'contact reduction', analogous to the 'contact exchange' proposed for cations in general by Jenny *et al.*[9], and that compaction works by increasing the area of contact. As is shown in Fig. 1, the roots growing in the compact soils were short and stubby as compared with those in the loose soils. Their irregular outlines indicate moulding by the tight-fitting soil. They also had far fewer hairs; this observation is at first surprising, but what seems to matter is the total area of contact rather than the existence of numerous points of contact. The total dry weight of root was always greatly superior in the compacted soils, being proportional to the above-ground weight.

Occasional observations have previously been made of better growth after rolling[10,11], but have been explained in the conventional way which we think is mistaken. Grey-speck of oats has always been known to be a patchy disease. This can be easily understood if it depends mainly on the compaction of the soil.

ISOLATION OF MALTOTRIOSE AND MALTOTETRAOSE FROM STARCH HYDROLYSATES

By A. G. CLARK

Beecham Food and Drink Division, Ltd., Beecham House, Great West Road, Brentford, Middlesex

AND

K. R. L. MANSFORD

Beecham Research Laboratories, Ltd., Brockham Park, Betchworth, Surrey

IN order to carry out gut perfusion investigations on the components of liquid glucose it was necessary to isolate dextrose oligosaccharides in 50-g quantities. The charcoal-'Celite' column chromatographic technique of Whistler and Durso[1] was applied to selected starch hydrolysates.

Analysis of commercial- and laboratory-made starch hydrolysates by the technique of Patterson and Buchan[2] revealed that the richest source of maltotriose was a laboratory-made starch hydrolysate using salivary amylase and maize starch. The richest source of maltotetraose was obtained by fermenting liquid glucose (high dextrose equivalent) with *Saccharomyces cerevisiae*. By these means the starting materials were prepared so as to contain about 30 per cent w/w of each oligosaccharide respectively.

The maltotriose-rich material was prepared as follows. Human saliva was collected, during stimulation from chewing paraffin wax, and centrifuged to remove the mucin. The saliva was stored at 0° C under toluene and used without further purification. About 15 ml. saliva was allowed to act on 200-g maize starch for 24 h at 30° C and *p*H 4·8. The reaction was stopped by boiling, followed by centrifugation to remove insoluble dextrins. The cyclone concentrated hydrolysate was stored at 0° C until required for application to the charcoal column. To prepare the maltotetraose rich material a seed culture of *Saccharomyces cerevisiae* (N.C.Y.C. 240) was sub-cultured in corn (maize) steep liquor (20 ml.), dextrose (50 g), and water (to 1 l.). The sub-culture was incubated with 100-ml. portions of high dextrose equivalent liquid glucose (special enzyme syrup prepared by Manbré and Garton, Ltd.) (200 g) containing urea (1·1 g), dipotassium hydrogen phosphate (1·1 g), potassium dihydrogen phosphate (0·7 g), magnesium sulphate (0·7 g), calcium chloride (0·2 g), and water (to 2 l.), at 20° C and *p*H 6·9. After 150 h the fermentation liquors were filtered to remove the yeast cells and cyclone concentrated prior to storage at 0° C.

The 36-in. column used for the separation work was composed of 460 g of charcoal (supplied by Sutcliffe, Speakman, Ltd., Leigh, Lancs., quality 130 in air-tight canisters) and 230 g of 'Celite', Johns-Manville grade 545, supported in a glass pipe of 2-in. diameter, and resting on a grade 2 porosity sintered glass disk. (The column is fabricated from standard Q.V.F. parts.) The whole column was surrounded by a water jacket, the connectors of which were coupled to the external circulator pump of a temperature-controlled bath, the temperature of which could be varied between 20 and 60° C. The top end of the column was closed by a reducing piece, held in place by standard flanges, and topped by a glass tube entering through a *B*24 standard joint secured by springs. The glass tube reached near to the surface of the carbon column. This tube was connected by a Y-piece to the lower liquid connexions of the two solvent reservoirs, containing the eluant, which were immersed in the water of the temperature-controlled bath. The gas connexions to these reservoirs were connected to a compressed air supply at 5 lb./in.^{2} and to a manometer and bubbler. The manometer reading served to confirm the gauge reading and the bubbler gave visual confirmation of a continuing gas supply. The lower end of the column was closed by a *B*50 standard joint fitted with a sintered glass disk which supported the column. This was in turn supported by a slotted panel cushioned with rubber. Below this section was a *B*19 standard joint supported by springs and fitted with a glass tap. The outlet of this tap led to a chain of fraction cutting T-pieces which operated with hydrostatically controlled non-return valves. These were fitted to litre collecting flasks, and the last flask was open-ended.

The column with the bottom parts well greased and securely connected was prepared as follows: the charcoal and 'Celite' were intimately mixed to a homogeneous powder, 2 l. of boiling distilled water were added with stirring, and the whole was thoroughly mixed to a homogeneous slurry. This was poured into the column and any entrained air was removed by agitating with a glass drumstick-shaped plunger, which was worked vertically to give a smoothly mixed slurry in the column. As more slurry was added, the plunger was removed and finally the last few portions of slurry were added as the column settled. When the column was full, the top fittings were well greased and securely connected and cold boiled distilled water passed through until at least 5 l. were collected. The top surface of the column should be just below the end of the main glass pipe. This surface was covered with a circular wire gauze disk supporting a filter paper disk.

The column was loaded by allowing the water-level to fall until it was immediately above the filter paper disk. The syrup or sugar solution containing about 25 g carbohydrate was added, by way of the opened standard joint, and allowed to drain into the column. As the level of the surface layer of syrup approached the column surface it was washed in with successive small amounts of boiled distilled water. The standard joint was then replaced securely and the eluant passed through the column at 5 lb./in.^{2} above atmospheric pressure. The eluant composition and the temperature were varied in accordance with requirements. The litre fractions were successively analysed by the orcinol method[3] for the presence of carbohydrate.

In order to elute maltotriose from the maltotriose-rich starting material, dextrose and maltose and any other mono- and di-saccharides were eluted simultaneously with 5 per cent aqueous ethanol at 40° C. When there was no further trace of carbohydrate in the eluate, maltotriose was eluted with 8 per cent aqueous ethanol at 40° C. Under these conditions the flow rate was about 450 ml./h and the maltotriose was collected in about 12 l. of eluate.

To obtain maltotetraose from the maltotetraose-rich material the lower oligosaccharides were eluted with 10 per cent aqueous ethanol at 40° C. Maltotetraose was then eluted with 12 per cent aqueous ethanol at 40° C. The elution of maltotetraose under these conditions was slow, and in order to complete the separation and preparation of dry material in a weekly cycle an attempt was made to accelerate the procedure by raising the temperature of operation to 50° C. This increased the flow rate to 600 ml./h, but the separation was incomplete and the early and late fractions had to be rejected because of traces of lower and higher oligosaccharides. The loss of maltotetraose involved was about 10 per cent. It was necessary to keep strict paper chromatographic control of the fractions and this was achieved with an overnight run on Whatman No. 1 paper in *n*-propanol, ethyl acetate, water (7 : 1 : 2) or more rapidly (3–4 h) on Whatman No. 1 paper in *n*-butanol, ethanol, water (2 : 1 : 1) at 60° C. The solution of isolated oligosaccharide was concentrated to about 200 ml. in a cyclone evaporator boiling at 20°–24° C under reduced pressure obtained by a water pump. The rate of evaporation was about 1 l./h and the concentrated eluate was freeze-dried.

Up to 30 per cent of the carbohydrate applied to the charcoal-'Celite' column was lost, apparently by irreversible adsorption. Even after desorption with hot 95 per cent ethanol complete recovery was not achieved. For this reason, and because the flow rate gradually decreases, the adsorbent was discarded after each run and the column reformed from fresh charcoal and 'Celite'.

Although the maltotriose and maltotetraose obtained as described were sufficiently pure for the purpose required there were isomeric oligosaccharides present in trace amounts, which were only detected by paper chromatography using Whatman 3*MM* paper and applying a 10 mg load. These substances appeared during the enzymatic treatment of the starch hydrolysate, whether by amylolysis or yeast fermentation. Maltotriose and maltotetraose can be obtained pure from commercial liquid glucose, but the yields will be very much smaller. It is possible to separate the maltotriose and maltotetraose from the contaminating oligosaccharides by the method of Barker *et al.*[4] using a charcoal column in presence of borate, but this technique has not been applied on a large scale. Another possible source of maltotriose is from the action of *Aureobasidium pullulans* on the polysaccharide pullulan[5], prepared from the organism *Pullularia pullulans*[6], which under suitable conditions hydrolyses this material specifically to maltotriose only

We thank Mr R K Opie and Mr A B Leah for assistance and Dr M Richards of the Microbiology Department at Brockham Park, who carried out the fermentation work We also thank Dr G Harris of the Brewing Industry Research Foundation for advice on the enzymatic and fermentation procedures and for arranging the supply of yeast from the N C Y C

ENZYMATIC ACTIVITY OF MOUSE HISTOCOMPATIBILITY ANTIGEN PREPARATIONS

By Dr A R. SANDERSON and Dr. D. A. L. DAVIES

Microbiological Research Establishment, Experimental Station, Porton, Nr Salisbury, Wilts

IT would be of interest to know what function transplantation antigens may serve in the cell and helpful for further purification and interpretation of the mechanism of graft rejection It is generally assumed that the same substance is being detected or measured by different test systems, for example, hastening skin-graft rejection, inducing hæmagglutinins or cytotoxins, inhibiting hæmagglutination or cytotoxic antibody and enhancing tumour growth in allogeneic mouse strains It appears that a more complete or undegraded form of material is required to affect skin grafts but the specificity can be followed further by serological methods, which have revealed that the substances are lipoproteins associated with the insoluble fraction of cells[1-3]

Fully active preparations have yet to be produced in a demonstrably homogeneous form; histocompatibility antigens can be prepared free from normal mouse serum components and cell-bound species-specific antigens[4], but evidence for physical homogeneity is not convincing It is not difficult to obtain a single schlieren band in the ultracentrifuge at alkaline pH or in the presence of some dispersing agent, but similar patterns can be obtained with preparations known from other evidence to be relatively crude So far preparations are probably mixtures of lipoproteins from various sub-cellular particles and membranes, some of which are likely to be inactive Such mixtures would be difficult to resolve on account of their essentially insoluble form, this suggests that the appropriate sub-cellular particle or fraction would make a more suitable starting material for purification The appropriate fraction is elusive, however, activity was largely in the nuclear fraction but also spread over mitochondrial, 'fluffy' and microsomal fractions when tested by tumour enhancement[5] By inhibition of cytotoxins, activity followed lysosomes, as indicated by acid-phosphatase activity[6], by skin-graft rejection, the microsome fraction was active[7], but in this case other sub-cellular fractions were not tested By hæmagglutinin induction microsomes and 'fluffy' layer are most active, but some activity is associated with nuclei and mitochondria though not with the soluble fraction[8] The suggestion[2] that activity is associated with external cell membranes the fragments of which may be distributed over a range of g time standard sub-cellular fractions has to be seriously considered

The preparation of high H-2 histocompatibility specific activity used here was prepared from ascitic fluid[1] and has these properties hastens skin-graft rejection[8], induces hæmagglutinins and cytotoxins[4,8,9] inhibits H-2 hæmagglutination and cytotoxic antibody[9,10] and carries non-H-2 specificity[11] Similar preparations from mouse leukæmic cells carry 'X' tumour specific antigenicity[12]

The lipoprotein nature of the material and its association with insoluble cell fractions suggested an examination for enzymes which are frequently associated with membranes Electron micrographs (× 62,000) have shown precise localization of nucleoside phosphatase in membranes[13], and the presence of 'ATPase' activity in our histocompatibility antigens was therefore not unexpected. In Table 1 are shown the activities which have been determined, it will be seen that nucleoside diphosphatase and triphosphatase levels are high compared with the other activities tested There is no consistent preference for any one of the four common ribonucleotide bases when used as substrate at the tri-, di-, or mono-nucleotide-level The triphosphatase activity figures are inaccurate to the extent that inorganic phosphate release was actually measured and the other product of hydrolysis, the nucleoside diphosphate, is then broken down (at a slower rate) with further inorganic phosphate release This error is minimized under the conditions used, where only a few per cent of the substrate was hydrolysed in order to avoid product inhibition, inaccuracy would only be significant with dissimilar K_m values

Table 1 PHOSPHATASE ACTIVITIES OF HISTOCOMPATIBILITY ANTIGEN PREPARATIONS

Substrate	pH	Activity*		
Adenosine 5′-phosphate	8 4	0 5		
Cytidine 5′-phosphate	8 4	0 8		
Guanosine 5′-phosphate	8 4	1 0		
Uridine 5′-phosphate	8 4	0 5		
Adenosine 3′-phosphate	8 4	0 6		
Adenosine 2′-phosphate	8 4	1 3		
Nicotinamide adenine dinucleotide	8 4	0 9		
Adenosine 5′-pyrophosphate	8 4		14 2	
Cytidine 5′-pyrophosphate	8 4		7 0	
Guanosine 5′-pyrophosphate	8 4		5 2	
Uridine 5′-pyrophosphate	8 4		7 0	
Adenosine 5′-triphosphate	8 4			20 0
Cytidine 5′-triphosphate	8 4			19 0
Guanosine 5′-triphosphate	8 4			13 5
Uridine 5′-triphosphate	8 4			15 3
Glucose 6-phosphate	6 2	0 4		
Glycerol 2-phosphate†	8 4	1 4		
Glycerol 2-phosphate‡	5 0	0 1		

Hexokinase was similarly shown to be absent (pH 8 4)

* All activities are expressed in mμmoles H_3PO_4 liberated per min/mg dry wt of enzyme preparation and are averages of several determinations done under optimal conditions of pH and metal ion requirements for the enzymatic activity being followed

† Conditions for alkaline phosphatase

‡ Conditions for acid phosphatase

Using ATP as substrate, the way in which nucleotide triphosphate activity followed histocompatibility activity on purification is shown in Table 2 A proper comparison of the two activities is difficult because one is using a highly accurate enzyme assay and a relatively inaccurate histocompatibility assay, hæmagglutination inhibition, where doubling dilutions give 50 per cent activity increments between adjacent tubes However, it can be seen that in each purification step the fraction having highest histocompatibility activity also has highest enzymatic activity The relatively poor histocompatibility activity of '*TM*' compared with '*SP*' fractions, which have more

Table 2. CORRESPONDENCE OF HISTOCOMPATIBILITY ACTIVITY AND TRIPHOSPHATASE ACTIVITY DURING ANTIGEN PURIFICATION (*C3H/BP8* PRODUCT)

Fraction[1]	Histocompatibility activity*	Triphosphatase activity†
AF	1	1
DP	100	8
DS	0	0
SP	500	33
SS	0	0
*TM*1	200	28
*TM*2	200	31
TT	0	/
TB	0	10

* Determined by *H*-2 hæmagglutination inhibition.

† Determined at optimal *p*H (8·4) and optimal metal ion requirement.

impurity, is probably due to their different states of dispersion[1].

Further properties of the triphosphatase are shown in Table 3. These indicate that the activity resembles that of a mitochondrial[14] and also of a seminal enzyme[15]. Differentiation from the activity described for another mitochondrial enzyme preparation[16] is afforded by the lack of dinitrophenol stimulation and sucrose inhibition, while the insignificance of the sodium and potassium enhancement of hydrolysis distinguishes this triphosphatase from others[17,18]. Finally, neither progesterone nor hydrocortisone[19] exerts any effect on hydrolysis.

Table 3. PROPERTIES OF THE ADENOSINE TRIPHOSPHATASE ACTIVITY

*p*H optimum (*tris*-buffer)		8·4	
Activated by	Mg^{++}	3·4 fold	over metal-free conditions
	Mn^{++}	2·3 fold	
	Ca^{++}	3·1 fold	
	Co^{++}	1·9 fold	
	Fe^{++}	1·8 fold	
Km (ATP)	$4\cdot0\times10^{-4}$M		

Activity unaffected by 2: 4 dinitrophenol, progesterone, cortisol, sucrose, sodium ions, potassium ions.

The *p*H stability, heat denaturation, periodate sensitivity, formaldehyde sensitivity and resistance to trypsin are similar for histocompatibility activity and enzymatic activity although it must be remembered that measurement of the former is subject to the limitations of a test using two-fold dilutions.

The very low acid phosphatase activity (Table 1) does not support the suggestion of an association of histocompatibility activity with lysosomes[6]; on the other hand, our antigen, being obtained from ascitic fluid, cannot correspond to any cell fraction prepared by normal cell disruption procedures in sucrose. Many different nucleotidases have been found in sub-cellular particles and membranes, distinguishable by various criteria. The characteristics may differ from one cell type to another (isozymes) so that our information does not yet indicate a cellular location. Nucleoside triphosphatase, as tested *in vitro*, is a purely destructive activity and presumably reflects a cellular process where an appropriate receptor is available, for example, transferase or permease. The impingement of an immune environment on such vital cell processes in grafted tisue might explain the dramatic nature of histocompatibility responses.

We thank Miss P. D. Marshall for excellent technical assistance.

HYPERPLASIA OF THE ISLETS OF LANGERHANS IN BREEDER RATS WITH ARTERIOSCLEROSIS

By PROF. BERNARD C. WEXLER and DR. CHARLES T. FISCHER

May Institute for Medical Research, Jewish Hospital of Cincinnati, and Department of Pathology, University of Cincinnati College of Medicine, Ohio

IT has been demonstrated that the glucocorticoids of the adrenal cortex exert a very significant effect on carbohydrate metabolism, that is, increased gluconeogenesis[1–3]. Chronic hyperadrenocorticism will produce diabetes, that is, steroid diabetes[3–4]. The diabetes seen in Cushing's syndrome[5], during pregnancy[6], in cases of excessive steroid treatment[7], or in experimentally induced steroid diabetes[8], does not respond readily to insulin. Further, steroid diabetes is different from pancreatic diabetes in that it is seldom associated with severe hyperglycæmia or ketosis, and the diabetes is often transient, disappearing promptly when the patient is relieved of steroid excess[9]. Despite these specific metabolic differences between steroid diabetes and diabetes mellitus, pronounced islet hyperplasia is found in both conditions[2,9].

The islets of Langerhans of the pancreas become hypertrophied and hyperplastic in diabetes[2], during pregnancy[6] in offspring of diabetic mothers[6], in patients with Cushing's syndrome[5], and in man and animals treated with ACTH or adrenal steroids[3,4,10]. This increase in islet size and number has been associated with increased demand and secretion of insulin. Chronic demand for insulin results in islet hypertrophy, progressive degranulation of the insulin-secreting beta cells, eventual hydropic degeneration and culminates with complete islet cell exhaustion[12,13].

We have been investigating experimental arteriosclerosis, which develops spontaneously in male and female breeder rats after repeated breeding[14–17]. The arteriosclerotic breeder rats also show low glucose tolerance when challenged with a glucose load[18]. These animals also showed evidence of hyperadrenocorticism and fatty infiltration of the liver, which became progressively more pronounced with successive breedings. It was of interest to learn if there were any alterations in the morphology of the islets of Langerhans which could be correlated with the number of breedings and the other pathological changes. Therefore, in the experiment reported here a number of animals were mated and afterwards killed so that a serial investigation could be made of the insular changes occurring in the pancreas of rats after 1–5 breedings. During the course of this experiment, it was found that these animals showed definite islet changes, arteriosclerotic lesions of the pancreatic vessels and pancreatitis.

Young adult males and female Sprague–Dawley rats were actively bred in our laboratory under controlled conditions. The time period for mating, gestation, nursing, and the few days of rest after weaning was kept constant throughout the breeding period. The mating partners were kept together throughout the experiment and were allowed to breed *ad libitum*. Of the initial 200 mating pairs there were 100 pairs which had had a similar breeding history, that is, the day of conception, delivery and size of litter being relatively constant. Most of the male breeders were so debilitated by the time they had sired four litters that it became necessary to kill them before they became further deteriorated. (Deterioration was evidenced by inactivity, loss of appetite, yellowing and loss of fur and the assumption of a humped position.) Male and female breeders were killed when the young were removed at weaning time (21 days after birth). Control animals consisted of virgin males (12 rats) and virgin females (12 rats) killed at the outset of the breeding experiment. Virgin rats of an age comparable to breeders do not develop arteriosclerosis. Further, to control the age factor, a similar group of twelve male and twelve female virgin rats was held, two rats of the same sex to a cage, and then killed as controls with the five-time breeder rats at the end of the experiment. All animals were housed in air-conditioned quarters. They were fed 'Rockland Rat Chow' *ad libitum*. No salt or fat was added to the diet.

Pancreatic tissue was removed and fixed either in 10 per cent buffered neutral formalin (Lillie) or in Zenker's fixative. Paraffin sections were cut at 3μ and stained with hæmatoxylin and eosin and with an aldehyde fuchsin trichrome stain to demonstrate beta cell granulation. Alcian blue, periodic acid Schiff stain, toluidine blue and Hale's stain were used to demonstrate metachromasia and mucopolysaccharides. Von Kossa's stain was used to demonstrate calcium.

To measure the increase in islet size and number with each breeding, sections were made of the pancreas of male and female rats in each breeding period, that is, 1–5 breedings. The number of sections examined microscopically in each case is given in Tables 1 and 2. The total number of islets larger than 25μ in any one diameter, in each section was counted. The long diameters of each of the first eight islets encountered in any given section were also measured and averaged. Finally, the total number of islets which exceeded 250μ in any given section was counted.

Table 1. EFFECT OF REPEATED BREEDING ON THE SIZE OF THE ISLETS OF LANGERHANS IN THE SPRAGUE–DAWLEY FEMALE RAT

	No. of sections*	Average No. of islets per section greater than 25μ	Size of islets in μ (mean ± *S.D.*)	Islets greater than 250μ (per cent)
Virgin controls (90 days old)	5	23·4	139 ± 29	7·7
First breeding	19	26·7	138 ± 34	7·5
Second breeding	14	24·9	136 ± 36	7·2
Third breeding	9	24·1	135 ± 27	7·8
Fourth breeding	15	26·4	156 ± 28	9·3
Fifth breeding	7	29·7	181 ± 36	18·3
Virgin controls (340 days old)	21	23·3	140 ± 28	7·3

* Each section of pancreas taken from a separate animal.

Table 2. EFFECT OF REPEATED BREEDING ON THE SIZE OF THE ISLETS OF LANGERHANS IN THE SPRAGUE–DAWLEY MALE RAT

	No. of sections*	Average No. of islets per section greater than 25μ	Size of islets in μ (mean ± *S.D.*)	Islets greater than 250μ (per cent)
Virgin controls (90 days old)	5	28·2	129 ± 26	8·5
First breeding	22	27·1	151 ± 36	10·6

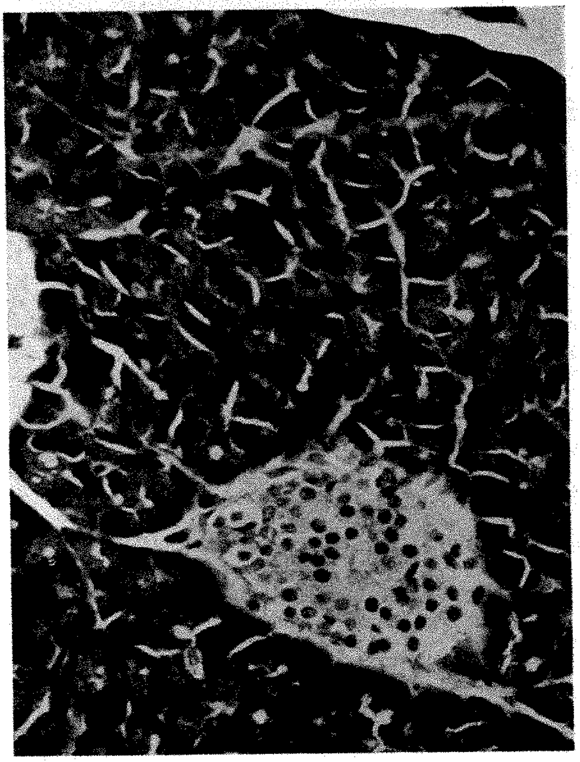

Fig. 1. Normal-sized islet in a virgin female Sprague–Dawley rat at 90 days of age. (Hæmatoxylin and eosin, × 200)

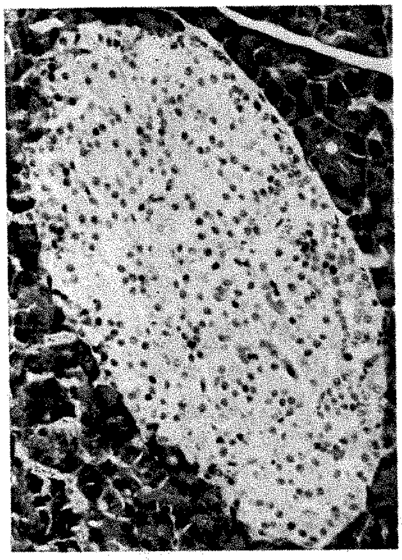

Fig. 2. Giant-sized islet in a female breeder rat (5 litters). (Hæmatoxylin and eosin, × c. 100)

Islet size. There was a definite increase in size and number of the islets of Langerhans in breeder rats compared with virgin controls (Tables 1 and 2). In the female breeders there was little change in average islet size after their first, second and third pregnancies. However, after their fourth and fifth pregnancies there was a definite increase in the number of islets larger than 25μ in each section, in the average size of islets in general, and in the percentage of giant islets, that is, greater than 250μ (Figs. 1–3). Male breeders, by contrast, had sustained (or developed) a marked increase in islet size and in the number of giant islets soon after their first litter. This situation continued throughout the course of the experiment, with an additional increase in the average size of islets after the fourth breeding. The increase in the average size of the islets in male breeders is even more meaningful if one considers the fact that male virgin control rats have smaller islets to begin with than female virgin rats (cf. Tables 1 and 2). That is, breeding effects a proportionately much larger increase in the size of islets in male rats, compared with non-bred males (virgins), than it does when non-bred females are compared with breeders.

Islet cytology. The alpha cells in the islets of the rat have a peripheral location. The more centrally located beta cells are much more numerous than the alpha cells. With continued breeding the alpha cells maintained their peripheral orientation and showed an increased definition of cell outline (Fig. 3). At the same time, the beta cells increased in number and had progressively increased in granulation. During this period of increased granulation, there was evidence of active ductular proliferation associated with generation of new islet tissue (Fig. 4). After the fourth to fifth breeding there was marked degranulation, hydropic degeneration and hyalinization in both male and female breeders. The hydropic beta cells were shown to contain glycogen, using Best's carmine stain.

Pancreatic arteries. Arterial lesions in the pancreatic arteries appear to be an extension of a more fulminating process which is initiated in the abdominal aorta[14]. In both the male and female breeders microscopic evidence of arterial lesions of the abdominal aorta and its branches appeared after the first breeding. Although the lesions in the main abdominal aorta showed involvement of both the intimal and medial layers, becoming more complicated with increased number of breedings, the pancreatic arteries showed only intimal changes (Fig. 5). These intimal changes in the pancreatic arteries consisted of either: (1) discrete endothelial cushions or endothelial proliferation involving a large portion of the intima accompanied by stretching of the internal elastic membrane; or (2) intimal basophilia without endothelial proliferation but accompanied by minor changes in the internal elastica (Fig. 5). Special stains of the basophilic material contained within the delicate intimal layer of the pancreatic arteries revealed that this basophilic material was intensely metachromatic and that it was an admixture of calcium and mucopolysaccharides.

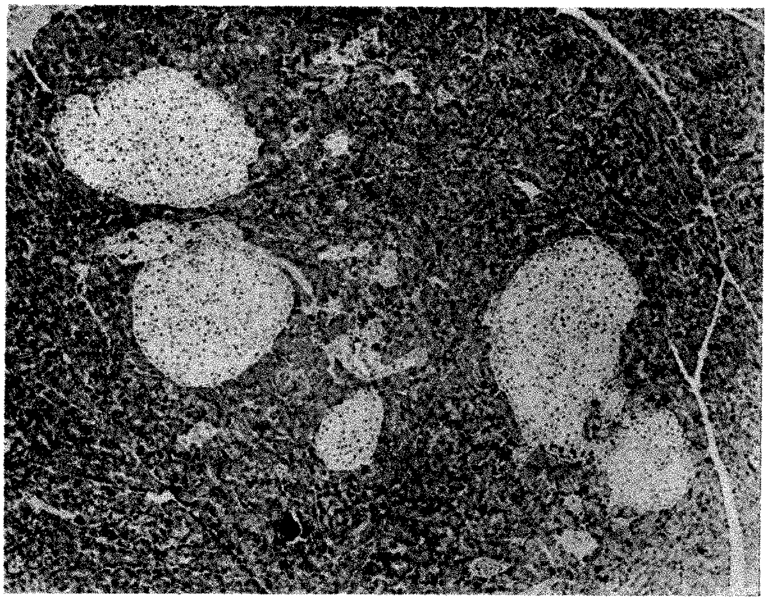

Fig. 3. Islet hyperplasia in a female breeder, bred five times. The peripheral alpha cells in the three giant-sized islets have prominent cell membranes. The beta cells are degranulated. (Hæmatoxylin and eosin, × *c*. 50)

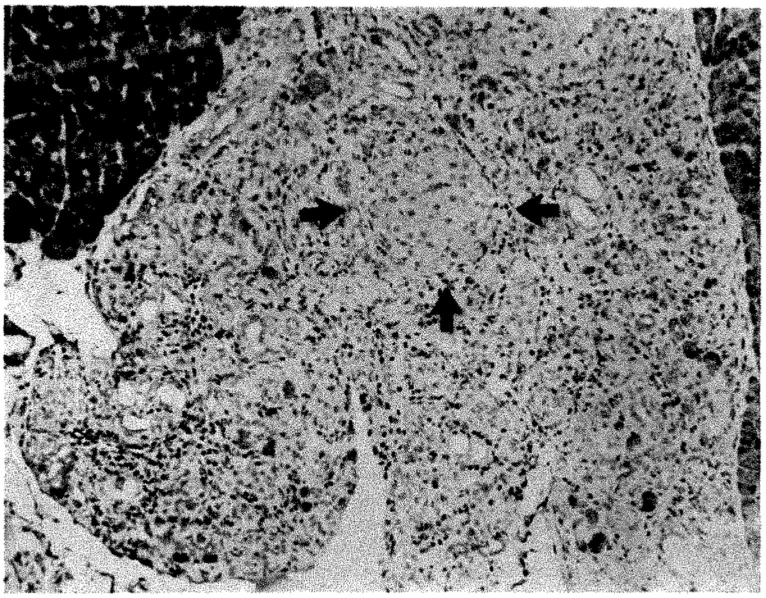

Fig. 4. Ductular proliferation in a male breeder rat showing newly formed islet tissue in the centre of the photo (see arrows). (Hæmatoxylin and eosin, × *c*. 100)

Pancreatitis and mixed islet and ductular proliferation. About the time of the third to fifth breeding, when islet hyperplasia and beta cell degranulation were becoming most pronounced, in many instances active ductular proliferation intermixed with hyperplasia of islet tissue occurred. In all instances, the ductular hyperplasia occurred in association with hyperplastic islet tissue (Fig. 4). The usual single intralobular ducts seen in the pancreas of the rat showed multiple branching. The hyperplastic islet tissue was often found entwined about these newly formed ductules. Islets of all sizes from small to giant size were found within these areas of ductular multiplication. The ratio of alpha to beta cells appeared to be normal in these newly formed islets.

After the fourth breeding, when definitive beta cell degeneration became evident, there was a concomitant reduction of the ductular proliferation which had become progressively more frequent during the second to fourth breeding. After the fourth breeding ductular proliferation began to wane until practically no cases of duct proliferation were encountered in animals bred five times.

Evidence of pancreatitis was found in 40 per cent of the male breeders and 25 per cent of the female breeders. The pancreatitis was characterized microscopically by œdema, necrosis, by marked infiltration of polymorphonuclear cells, some fatty infiltration, and, in more advanced cases, by calcification particularly about the periphery of the pancreas (Fig. 6).

The increase in number and size of islets with breeding shown here is particularly meaningful in that other experiments have shown that breeder rats have low glucose tolerance[16]. That is, the increases in islet size and number are either a response to the stimulus of the abnormal carbohydrate metabolism in these breeder rats, or the islet changes *per se* are the cause of the spontaneous development of diabetes. It is more likely that the islet

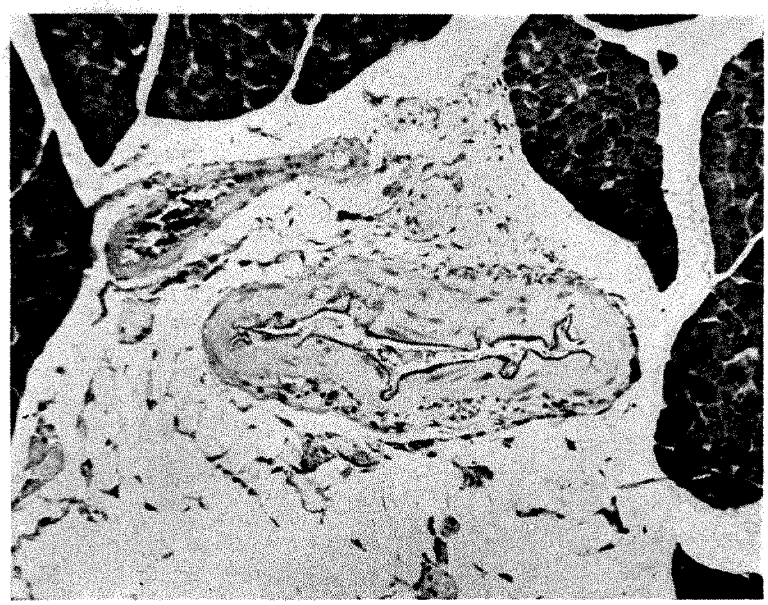

Fig. 5. Pancreatic artery showing heavy concentration of basophilic material in the intima. This material is intensely metachromatic, intensely positive with the Hale and Von Kossa stains and is believed to be an admixture of mucopolysaccharides and calcium. (Hæmatoxylin and eosin, × c. 100)

hyperplasia is an attempt by the pancreas to compensate for the increased adrenocorticoid activity which accompanies the progressive development of diabetes, hypertension and arteriosclerosis in repeatedly bred rats. In experiments to be published soon the adrenal cortices of these breeder rats have been found to show progressive hypertrophy and lipid depletion with successive breedings and concomitant with the development of arteriosclerosis. Also, the thymi in breeder rats become severely involuted during progressive breeding. Further, *in vitro* investigations of the alpha-ketolic steroid production of adrenal glands from breeder rats show definite derangement of adrenal steroid production. The changes in the adrenal glands, both biochemically and histologically, coupled with the severe thymic involution demonstrate to us that the adrenal glands of breeder rats are actually producing steroids in abnormal amounts.

Many investigators believe that the islets of Langerhans have a capacity for compensatory increased production of insulin and are able to meet unusual demands for insulin so long as this resiliency on the part of the islets is maintained[11]. However, under unusual conditions, for example, excess glucose mobilization due to overabundant secretion of glucocorticoids, this insulin reserve may break down. Or, if the islets are capable of hyperplasia and produced increased amounts of insulin, the hyperglycæmia may remain undetected. In this same connexion, ancillary studies show that male breeder rats probably have a more severe defect in their carbohydrate metabolism than female breeders because their glucose tolerance curve shows a much more severe hyperglycæmia 1 h after glucose loading than female breeders[18]. It is suggested that the islets of the female breeder probably have a greater functional reserve capacity than the male breeders. It is interesting that islet hyperplasia occurs soon after the first breeding in the male; but the stimulus for increased islet hyperplasia in the female does not become evident until well after the fourth or fifth breeding. Increase in islet size has been demonstrated by Hellman to occur with age[19]. However, the size of the islets in virgin rats (controls) of the same age as the breeders was only slightly larger than the younger virgin control rats killed at the outset of the experiment.

The specific cytological changes in the islets permit an even closer correlation with the physiological events taking place than the changes in islet size. Up to the fourth breeding the beta cells showed progressively increased granulation, in both sexes. This could be construed as being indicative of a compensatory response on the part of these cells to produce increased amounts of insulin. One could extrapolate, however, that this response was not adequate because: (1) these animals become hyperglycæmic[18]; (2) ductular elements showed proliferation to produce more islet tissue; (3) existing islets underwent progressive hyperplasia in an attempt to produce more beta cells. Further, it is felt that the demands of continued breeding finally caused exhaustion of these beta cells as demonstrated by their rapid degranulation after the fourth breeding.

Glucose tolerance tests conducted on breeder rats have revealed that these animals are not severely hyperglycæmic[18]. Rather, it appears that they are more likely in a mild diabetes-like state which would best fit the condition of hyperadrenocorticism found in these breeders. Although these animals do not have any marked elevation of serum cholesterol until arteriosclerosis is well advanced, they do have a progressive fatty infiltration of the liver at the same time that they show abnormal tolerance to glucose and begin to show evidence of arteriosclerosis[14]. One could perhaps best rationalize these many metabolic disturbances as being part of a syndrome which is much like that seen in Cushing's disease or in human pregnancy[5,6], that is, islet hyperplasia, fatty liver, diabetes and arteriosclerosis are all concomitants of Cushing's syndrome[5].

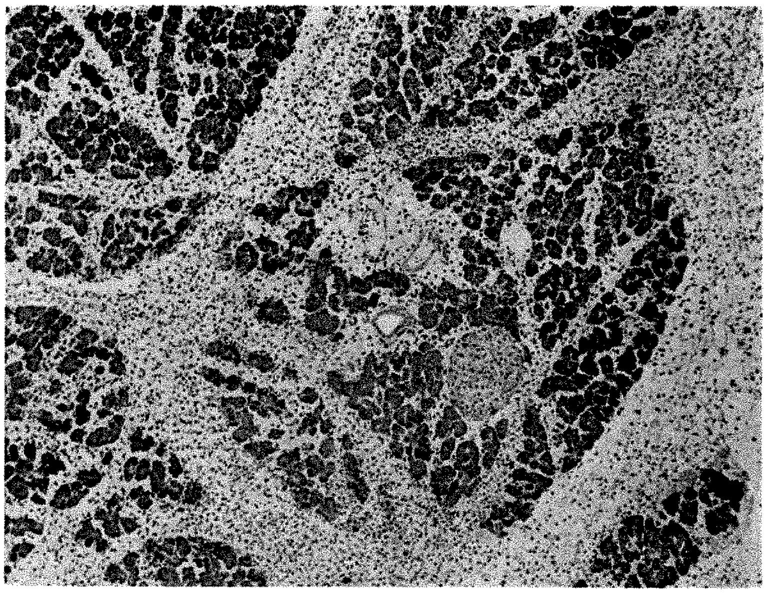

Fig. 6. Severe pancreatitis in a repeatedly bred male rat (sired four litters). Note the round cell infiltration and the marked œdema which separates individual acini. Fatty necrosis and calcification (not shown here) were found in peripheral portions of this organ. (Hæmatoxylin and eosin, × c. 50)

It is particularly interesting that the morphology of the arterial lesions in the larger branches of the abdominal aorta was distinctly different and much more severe than those in the parenchyma of the pancreas itself The intimal accumulation of mucopolysaccharide–calcium complex in these pancreatic arteries is typical of the arterial lesions in arteries of similar calibre in organs served by the intestinal arteries

Ductular proliferation and budding-off of islet tissue have been demonstrated to occur during fœtal life and in the post-natal period Several authors have cited evidence to indicate that this ductular response to form new islet tissue may be under hormonal control For example, Ogilvie and Maclean have shown striking increases in pancreatic duct growth and generation of islet tissue in rabbits in association with marked changes in the adrenal cortices of these same animals[20] The hormones of the anterior pituitary gland, for example, growth hormone and adrenocorticotropin, have also been demonstrated to elicit these changes[21,22] The connexion between the anterior pituitary gland and its hormones has been cited for two reasons First, the ductular proliferation becomes progressively more intense with each breeding, which would implicate pituitary gland participation, and also the ductular proliferation suddenly becomes quiescent at the time when these particular animals become incapable of producing more litters Secondly, it is well known that pancreatitis appears after periods of stress, or can be induced by ACTH excess[23], and in advanced cases of Cushing's disease purulent pancreatitis, fatty necrosis and infarction are evident in the pancreas[24,25] It is possible that the disappearance of ductular proliferation and appearance of many cases of pancreatitis in these breeders is connected with some marked change in the function of the pituitary gland The higher incidence of pancreatitis in the male breeders (40 per cent versus 25 per cent in females) may also explain the earlier demise of the male breeders after the fourth breeding

In conclusion, it is felt that repeated breeding in rats leads to metabolic alterations which resemble conditions seen in Cushing's syndrome and in human pregnancy The hyperglycæmia[18], the islet hyperplasia, the beta cell granulation and eventual exhaustion are all indicative of a persistent demand, most likely due to adrenal steroid excess; for increased secretion of insulin culminating in eventual exhaustion of the islet cells Further investigation will be required to correlate the possible relationship between the simultaneous development of hyperglycæmia and arteriosclerosis in these breeder rats The tentative explanation for this phenomenon will remain implicit within the broad concept that this arteriosclerosis and abnormal carbohydrate metabolism are part of a Cushingoid condition existing in these animals

VISUAL PIGMENTS IN HUMAN AND MONKEY RETINAS

By PAUL K. BROWN and Prof GEORGE WALD

Biological Laboratories of Harvard University, Cambridge, Mass.

ONE of the major problems in the field of vision is to define the photosensitive pigments of the cones which serve for colour vision in man and other primates, and to establish the associated spectral sensitivity curves of the colour vision receptors One cannot derive this information from traditional types of sensory measurement, for an almost infinite variety of trios of theoretical sensation curves can be devised which satisfy virtually all the sensory data[1] The problem, therefore, is not to invent further models that might account for colour vision, but to find the actual mechanisms that serve this function

Stiles seems to have come closest to solving this problem with specially designed sensory measurements (his "two-colour threshold technique") Some years ago, using this method on his own eye, he derived three sensitivity curves maximal at about 440, 540, and 590 mμ (ref 2) Most measurements since have tended to conform with these values

So, for example, Auerbach and Wald[3], following adaptation of the eye to intense orange light, measured the spectral sensitivity of a 'violet receptor', maximal at about 440 mμ The spectral sensitivity of the human fovea, particularly when dark adapted or in dim light, is reported to display inflections at about 430–450, 540–560 and 590–620 mμ, suggesting the presence of sensitivity maxima within these wave-length ranges[4]

Rushton[5] made a notable advance in this field by measuring directly the difference spectra of human colour vision pigments with light reflected from the fundus in living human eyes He has described a green-sensitive pigment ('chlorolabe') maximal at about 540 mμ, and a red-sensitive pigment ('erythrolabe') at about 590 mμ Weale[6], using similar methods, reports pigments maximal at about 540 and 600 mμ

This article describes measurements of difference spectra of the retinal photopigments of man and the monkey (rhesus, *Macaca mulatta*), performed with the

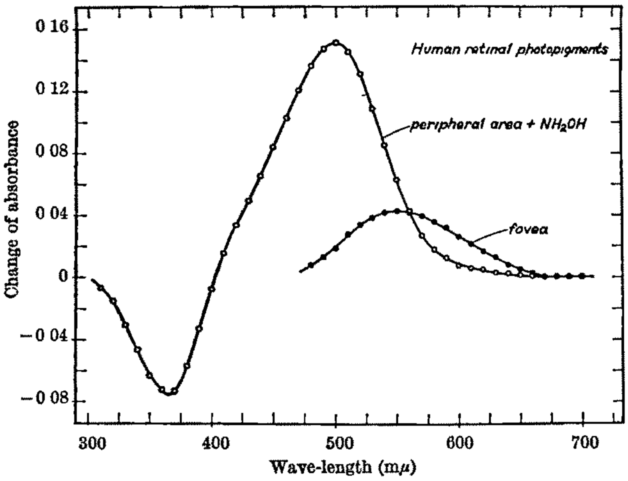

Fig 1 Difference spectra of photosensitive pigments in the human retina ●, total pigments of the rod-free area of the fovea The difference spectrum has λ_{max} about 550 mμ and E_{max} 0 042, ○, total bleaching of a rod-rich peripheral area of the retina, measured in the presence of 0 1 M hydroxylamine The difference spectrum is that of rhodopsin (λ_{max} 500 mμ), the bleaching of which yields retinal as product This combines immediately with hydroxylamine to yield retinaldehyde oxime, which accounts for the minimum at about 367 mμ

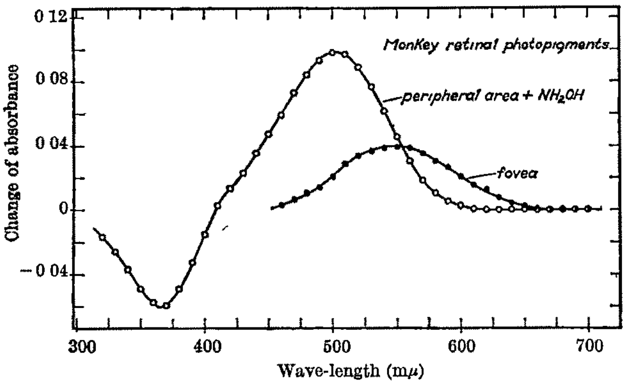

Fig 2 Difference spectra of photosensitive pigments in the retina of the rhesus monkey ●, the total bleaching of the central fovea (λ_{max} about 550 mμ) This fovea yielded also the data of Figs 3 and 5, ○, bleaching of a rod-rich peripheral area in the presence of 0 1 M hydroxylamine The difference spectrum is that of rhodopsin, with λ_{max} about 502 mμ The retinal liberated as a product of bleaching combines at once with hydroxylamine to yield retinaldehyde oxime, accounting for the minimum at about 367 mμ

recording microspectrophotometer already described[7] Circular areas of the retina were measured, 0 2 mm in diameter Such measurements made in a rod-rich area outside the fovea yielded the familiar difference spectrum of rhodopsin (Figs 1 and 2), earlier shown to match closely in the visible region the scotopic sensitivity of human vision, measured at the retinal surface[8] When the field of measurement lay inside the rod-free area of the fovea, which is about 0 5 mm in diameter in man and 0 2 mm in the monkey[9], a total difference spectrum was obtained, maximal at about 550 mμ (Figs 1 and 2) This matches closely the photopic sensitivity curve of human vision, corrected for absorption of light by the ocular tissues and the yellow macular pigmentation (Fig 8) On differential bleaching of the central fovea with lights ranging between deep red and orange, the total difference spectrum can be shown to include contributions from a red-sensitive pigment with λ_{max} about 565 mμ, and a green-sensitive pigment with λ_{max} about 535 mμ (man) or about 527 mμ (monkey) Some indication was obtained also of a small amount of a third pigment, bleaching maximally at about 440 mμ, though other evidence indicates that the fovea contains such a pigment, our measurements do not identify it reliably

Human eyes, obtained from an eye bank, were from persons 40–70 years of age All of them had been light-adapted to some degree at the time of removal Ordinarily they were placed in light-tight containers shortly after enucleation, and kept cold until called for, usually 4–5 h and never more than 12 h later We found that in fresh eyes the retina tends to cling to the vitreous, so the eyes were always kept cold for a total of about 12 h, after which the retina separates readily

Monkeys were blindfolded about 0 5 h before being killed, and the eyes were removed in deep red light, so that these retinas were genuinely dark adapted Measurements with one retina were begun within 2–3 h The other eye in a light-tight container was placed in a deep-freeze, and kept frozen until used, sometimes months later When such an eye is thawed quickly by immersion in warm water, the retina can be dissected out whole, and yields measurements not very different from those obtained with fresh retinas Fig 3 shows measurements made with such a previously frozen retina

All the operations to be described were performed in deep red light The eye, held by the stump of the optic nerve, is cut around the bulbus well behind the equator. The rear portion of the eye is immersed in normal saline solution in a flat glass dish, and the retina released by cutting through the point of attachment to the optic nerve The retina is spread out at the bottom of the dish, under saline, with the receptor cells pointing upward On viewing it over a very dim blue light, the macular region can be seen as a dark patch with a lighter spot near its centre that marks the fovea A more-or-less circular patch of retina about 3–4 mm in diameter containing the macular region is cut out with scissors and forceps and transferred to the microcell previously described (a quartz cover slip holding a plastic ring about 0 4 mm high)[7] One drop of 55 per cent glycerol in normal saline solution fills this cell, which is then closed with a second quartz cover slip The cell is placed on the stage of a low magnification microscope ('macroscope', see ref 7), and is aligned under deep red light (675 mμ) so that the central fovea lies just over a circular diaphragm, 0 08 mm in diameter, which delimits an area 0 2 mm in diameter at the level of the receptors After this preliminary alignment, a compound microscope of magnification 100 times is brought over the microcell, and the alignment further adjusted if necessary All these manipulations are carried

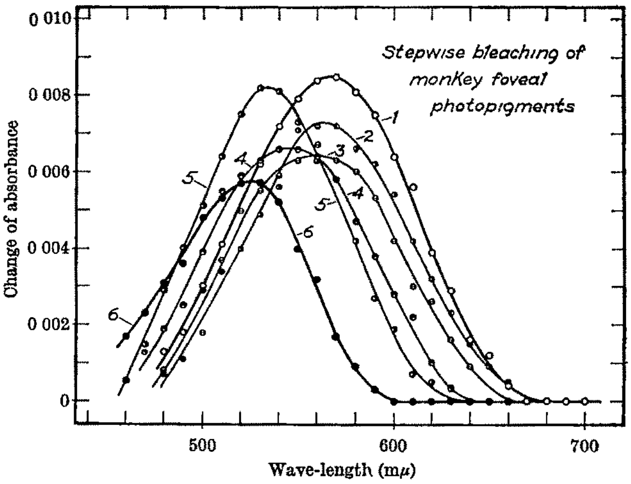

Fig 3 Difference spectra from a monkey fovea, associated with the bleaching of photosensitive pigments by short flashes of light transmitted through a progressive series of red cut-off filters The flashes had a half-duration of 120 msec The filters used in the successive bleaches were selected from the combinations listed in Table 1, and transmitted all wave-lengths longer than the following cut-off values (1) Combination 2 675 mμ, (2) Comb 3 665 mμ, (3) Comb 4 655 mμ, (4) Comb 5 645 mμ, (5) Comb 6 615 mμ, (6) Comb 7 595 mμ In constructing Fig 5, curve (1) has been taken as the spectrum of the red-sensitive pigment, and curve (6) as that of the green-sensitive pigment, while the sum of all the curves yields the total difference spectrum

out as rapidly and with as little exposure to red light as possible

Spectra are recorded in the microspectrophotometer as described previously[7]. It usually takes 0 5–1 h after the retina has been immersed in glycerol-saline to achieve a stable baseline The tissue is kept completely dark except during a recording, and the recording itself does not involve any measurable bleaching of the tissue The spectrum is recorded first using the ordinary 0–1 density range of the instrument in order to observe its general characteristics There is usually a large baseline absorption, mainly owing to the yellow pigmentation of the macula, shown some years ago to be due to the carotenoid xanthophyll[10] This is approximately balanced out in the reference beam by a solution of crystalline leaf xanthophyll in a mixture of carbon disulphide and chloroform (20 80), in a cell of adjustable depth[11] The xanthophyll had been heat-isomerized previously by melting the crystals, so as to produce a mixture of *cis* and *trans* isomers, the absorption spectrum of which in this solvent resembles closely that of the human macular pigmentation (cf Fig 8) After a retina had been balanced against the xanthophyll solution, the spectrophotometer was shifted to a 0–0 1 slide wire, so magnifying its absorbance scale ten times

The spectrum of the retina is recorded, first in the dark, and then after exposure to various lights By subtracting spectra of the bleached or partly-bleached tissue from spectra recorded earlier, the difference spectra shown in this paper are obtained

Bleaching was accomplished in one of three ways· (1) With 6 6 mμ wave-bands from a Bausch and Lomb monochromator, using a 100-W zirconium arc as source (2) With short flashes from standard *M*5 clear photographic flash lamps, transmitted through various colour filters Oscilloscope observations showed the output of these lamps to be remarkably constant, the half-duration of each flash being about 120 msec (3) With the focused light of a tungsten filament lamp in a Bausch and Lomb Nicholas illuminator, passing through colour filters.

The colour filters were all of the cut-off type, transmitting all radiation longer than a specified wave-length Each of them was tested carefully to be sure that it had no radiation leaks below the cut-off wave-length These filters were used always in combination with a Jena *KG* 1 heat filter Their characteristics are listed in Table 1

Table 1 THE CUT-OFF WAVE-LENGTHS ARE THOSE AT WHICH THE FILTERS TRANSMIT 1 PER CENT OF INCIDENT RADIATION J, JENA (SCHOTT), W, WRATTEN (EASTMAN KODAK), C, CORNING THESE FILTERS WERE USED ALWAYS IN COMBINATION WITH A JENA *KG* 1 HEAT FILTER

Filter	Cut-off wave-length (mμ)	Filter	Cut-off wave-length (mμ)
(1) J *RG* 10	690	(7) J RG 1	595
(2) J *RG* 8	675	(8) J OG 3	570
(3) W 36+C 3480	665	(9) J OG 2	550
(4) W 35+C 3480	655	(10) J OG 5	535
(5) J *RG* 5	645	(11) C 3384	490
(6) J *RG* 2	615	(12) C 3385	465
		(13) C 3387	442

All these measurements were carried out at room temperature, usually about 25° C No special attempt was made to supply the tissue with oxygen Though isolated retinas rapidly turn cloudy in saline or Ringer solution, in saline-glycerol mixtures they remain reasonably clear The base line was usually found to remain fairly stable for periods of about half an hour, sometimes longer

Peripheral retina rhodopsin Several measurements were made in areas of retina well outside the fovea In such cases hydroxylamine was added to the glycerol-saline in a final concentration of 0 1 M After recording the spectrum in darkness, the tissue was bleached with orange light, and the spectrum again recorded

Difference spectra so obtained from human and monkey retinas are shown in Figs 1 and 2 In both cases the familiar difference spectrum of rhodopsin was obtained The observation that human rhodopsin in the retina has λ_{max} 500 mμ agrees with measurements previously made on suspensions of human rod outer segments[8] The λ_{max} in the monkey came out slightly higher, at about 503 mμ The bleaching of rhodopsin yields a mixture of opsin and retinal (formerly retinene) as products, the latter immediately combining with hydroxylamine to yield retinaldehyde oxime (λ_{max} 367 mμ) The curves in Figs 1 and 2 display minima at about 367 mμ, owing to the formation of this product

The maximum extinction (E_{max}) of human rhodopsin varied considerably from retina to retina Our highest extinction, shown in Fig 1, was 0 15, equivalent to about 30 per cent absorption This agrees almost exactly with Rushton's estimate[12] of the extinction of rhodopsin in human rods

The highest extinctions of rhodopsin measured in monkey retinas were about 0 10, corresponding to about 20 per cent absorption It will be recalled that the monkey retinas were dark adapted, whereas we had no such assurance in the human tissues

When rhodopsin is bleached in solution in the presence of hydroxylamine, the rhodopsin maximum at about 500 mμ comes out almost exactly equal in height to the retinene oxime minimum at 367 mμ Recent spectrophotometric measurements on frog and cattle retinas yielded a quite different result—the retinene oxime minimum was considerably smaller than the rhodopsin maximum The reason is that in the rods the rhodopsin molecules are oriented so that their chromophores lie perpendicular to the long axis of the outer segment, and so absorb more strongly than in solution, whereas the retinene oxime formed on bleaching not only loses this orientation, but orients partly in the axial direction, so absorbing less strongly than in solution[13] The difference spectra of rhodopsin in human and monkey retinas display much the same type of relationships as observed in frog and cattle retinas, implying somewhat the same plan of molecular orientations.

Fovea: total bleaching. The difference spectra obtained by completely bleaching the photosensitive pigments of human and monkey foveas are shown in Figs 1 and 2 In both cases the difference spectra are maximal at about 550 mμ No hydroxylamine was used in these instances, so that the product of bleaching is retinaldehyde rather than retinaldehyde oxime Since, however, retinaldehyde does not absorb appreciably at wave-lengths longer than about 510 mμ, above this wave-length these difference spectra have the force of genuine absorption spectra

In both man and monkey the maximum density of the total foveal pigment that we observed was about 0 04, corresponding to about 9 per cent absorption This is about half the density reported for the total cone pigments by Rushton[5] One might ascribe this discrepancy to the fact that Rushton's measurements were made on wholly dark-adapted subjects, whereas our human retinas may have been partly bleached On the other hand, our rhodopsin measurements in human retinas agree exactly with Rushton's; and our monkey retinas, which were wholly dark adapted, yielded the same result

Fovea colour vision pigments We have attempted to fractionate the foveal photopigments into their components by differential bleaching with coloured lights This was done in two ways, illustrated in Figs 3 and 4

In the first procedure the retinas were exposed to the light from flash bulbs, as described in bleaching method (2) aforementioned, coming through a progressive series of red cut-off filters (cf Table 1)

Fig 3 shows such an experiment on a monkey fovea The first flash contained only wave-lengths longer than about 675 mμ, and caused a bleaching represented by difference spectrum (1), with λ_{max} about 568 mμ The second flash contained wave-lengths above about 665 mμ, and yielded difference spectrum (2), with λ_{max} about 564 mμ The third flash, cutting off at about 655 mμ, yielded difference spectrum (3), with λ_{max} about 560 mμ It should be noted that these first three bleaches with

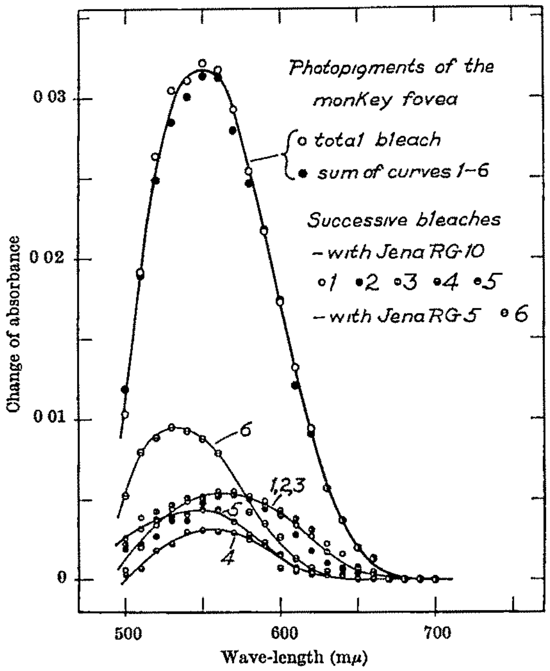

Fig 4 Difference spectra associated with the bleaching of photopigments of the monkey fovea in continuous red light. Curves 1–3, obtained by bleaching through a filter combination that transmits only wave-lengths longer than 690 mμ, involve primarily the bleaching of the red-sensitive pigment, with λ_{max} about 565 mμ Further exposure to the same deep red radiation bleaches in addition larger and larger proportions of the green-sensitive pigment (curves 4 and 5) The final bleaching with a filter combination transmitting above about 645 mμ involves virtually the green-sensitive pigment alone (λ_{max} about 533 mμ) The large open circles show the difference spectrum of the total bleaching of this fovea, the solid circles the sum of curves 1–6 The good agreement between these last two sets of measurements shows that all these difference spectra represent pigments present in the fovea originally, none of them could represent some new photosensitive product of the prior bleaching of one of the other pigments

deep red flashes yielded quite similar difference spectra, λ_{max} varying only between 560 and 568 mμ

The fourth flash, which contained wave-lengths above about 645 mμ, yielded a highly displaced difference spectrum, with λ_{max} about 546 mμ (curve 4) The fifth flash, cutting off at about 615 mμ, yielded a difference spectrum maximal at about 534 mμ (curve 5) The sixth and last flash, cutting off at about 595 mμ, yielded a smaller bleaching with λ_{max} about 526 mμ Exposure of the retina to further flashes at still shorter wave-lengths produced no measurable further bleaching.

It should be noted that curve 6 in Fig 3 displays no appreciable absorption at about 620 mμ, where curve 1 displays a strong absorption It can be expected for this reason that the filter used for exposure 1 should have bleached little if any of the pigment represented by curve 6 (Very small amounts of the latter pigment do seem to have been bleached in exposures 2 and 3, accounting for the small progressive shift of λ_{max} in each of these curves toward shorter wave-lengths) These measurements suggest that two pigments are involved, a red-sensitive pigment represented approximately by curve 1, and a green-sensitive pigment represented approximately by curve 6, the intermediate curves representing the bleaching of various proportions of both pigments

A computation based on this presumption is shown in Fig 5 The total difference spectrum obtained by adding together curves 1–6 in Fig 3 is shown as the uppermost curve in Fig 5 (curve 1) We assume that curve (1) of Fig 3 represents a red-sensitive pigment which accounts for the entire absorption in the total difference spectrum above about 625 mμ On this basis we adjust the height of curve 1 from Fig 3 so that it coincides in Fig 5 with the total difference spectrum above this wave-length (curve 2) If it is true that only two photosensitive pigments contribute to the total difference spectrum, subtracting curve 2 from the total might be expected to yield the spectrum of the other pigment This is shown in Fig 5 with open circles and a broken line (curve 1–2) It has λ_{max} about 530 mμ We have also drawn into Fig 5 the spectrum of the last bleach (curve 6) in Fig 3, giving it the same height as curve 1–2 (small closed circles and solid line) It has λ_{max} about 526 mμ

It is evident from this computation that the propositions expressed previously hold reasonably well Subtracting the spectrum of the most red-sensitive pigment from the total yields a spectrum close to that of the green-sensitive residue

In Fig. 5 the red-sensitive pigment has a maximal extinction about 1 5 times as high as the green-sensitive pigment Of five monkey foveas measured, four displayed about this proportion of red- and green-sensitive pigments, the fifth had these pigments in the reverse proportions, about 3 green- to 1 red-sensitive

The results of bleaching a monkey fovea in continuous red light (bleaching method 3 aforementioned) are shown in Fig 4 The retina was exposed for successive intervals to the focused light of a tungsten filament lamp passing through the Jena *RG* 10 filter, which transmits all wave-lengths longer than 690 mμ The difference spectra obtained in five successive exposures to this radiation are shown as curves 1–5 The first three exposures yielded very similar difference spectra, with λ_{max} about 563 mμ We take this to represent the red-sensitive pigment The fourth exposure yielded a much smaller bleaching, with λ_{max} displaced to about 557 mμ By this time most of the red-sensitive pigment had been bleached, and the green-sensitive pigment had begun to bleach Exposure 5, which was just as long as exposure 4 but at three times the intensity, caused a further bleaching with λ_{max} about 550 mμ, the curve had also broadened considerably toward shorter wave-lengths By now the red-sensitive pigment must have been almost wholly bleached, and a relatively high proportion of green-sensitive pigment was bleaching Finally the retina was exposed to the light passing through a Jena *RG* 5 filter, which transmits all wave-lengths longer than about 645 mμ This resulted in the bleaching shown in difference spectrum 6, with λ_{max} about 533 mμ, which we take to represent approximately the spectrum of the green-sensitive pigment

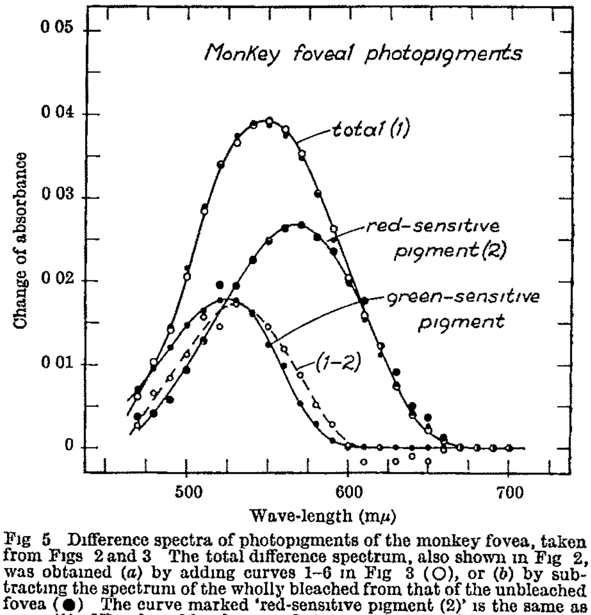

Fig 5 Difference spectra of photopigments of the monkey fovea, taken from Figs 2 and 3 The total difference spectrum, also shown in Fig 2, was obtained (*a*) by adding curves 1–6 in Fig 3 (○), or (*b*) by subtracting the spectrum of the wholly bleached from that of the unbleached fovea (●) The curve marked 'red-sensitive pigment (2)' is the same as curve (1) of Fig 3, and has been made to coincide in height here with the total difference spectrum in the red region in which the red-sensitive pigment alone absorbs light appreciably Subtracting curve (2) from (1) might then represent the difference spectrum of the green-sensitive pigment (broken line, 1–2), this has λ_{max} about 530 mμ It is to be compared with the difference spectrum obtained directly as curve 6 of Fig 3, which has λ_{max} about 525 mμ

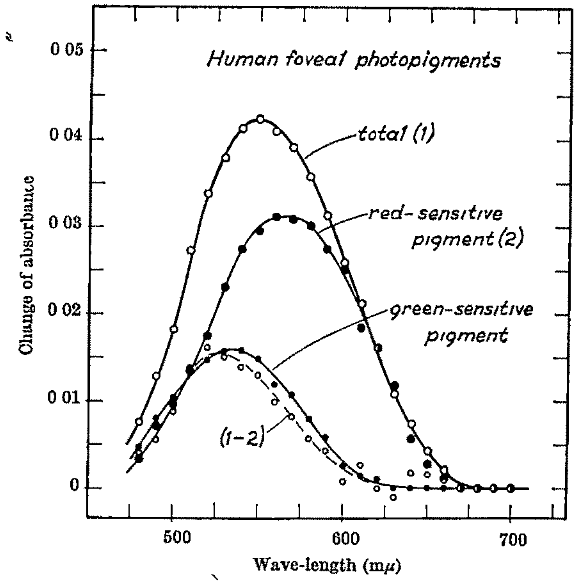

Fig 6. Difference spectrum of photopigments of the human central fovea. The difference spectrum of a red-sensitive pigment (curve 2, λ_{max} 565 mμ), obtained by differential bleaching in deep red light, accounts for virtually all the absorption at wave-lengths longer than about 625 mμ. It is adjusted in height, therefore, so as to coincide with the total difference spectrum (1) above this wave-length. Subtracting curve 2 from 1 should then yield the difference spectrum of the green-sensitive pigment, this is shown as a broken line (1–2) with λ_{max} about 530 mμ. It is to be compared with the directly measured difference spectrum of the green-sensitive pigment, shown with a solid line (λ_{max} about 535 mμ), obtained at the end of a successive series of bleaches with red light as in Fig 3.

It has been reported that some products of the bleaching of visual pigments in the living cat are themselves photosensitive[14], and similar effects have been reported also with visual pigments in solution[15]. On some such basis one might raise the question whether the green-sensitive pigment shown in Fig 5 could itself be a product of the bleaching of the red-sensitive pigment.

Apart from the fact that retinal in all circumstances is subject to isomerization by light, the only photosensitive product of the bleaching of rhodopsin we have yet observed in our laboratory involves the appearance of a pigment with λ_{max} about 467 mμ derived from metarhodopsin II when the latter is present in high concentration[16]. The 467 mμ pigment is unstable both in light and darkness, and can be observed only under quite special conditions. Neither this nor any other light-sensitive pigments of bleaching appeared in the course of the present measurements.

The data of Figs. 4 and 5 show this to be so. The tall curve in Fig 4 shows with open circles the difference between the spectra of the unbleached and wholly bleached fovea, and with solid circles the sum of the partial difference spectra 1–6. Similarly the 'total' curve 1 in Fig 5 shows with solid circles the difference between the spectra of the unbleached and wholly bleached fovea, and with open circles the sum of the partial difference spectra 1–6 in Fig 3. If in either case any of the partial difference spectra represented a new pigment derived from a prior bleaching, the partial difference spectra could not possibly add up to that representing the total bleaching, but must on the contrary yield a larger sum. The fact that the summed-up difference spectra add almost exactly to the total difference spectrum demonstrates that all the pigments bleached in this experiment were present in the retina originally. The degree to which the difference between the spectrum of the red-sensitive pigment and the total in Fig 5 (1–2) matches the directly measured spectrum of the green-sensitive pigment tends toward the same conclusion, and the similar experiment on human foveal pigments shown in Fig 6 bears on the same point.

It is therefore plain that the pigments differentially bleached in these experiments were present in the original tissue. The observations imply the presence of two such pigments in the monkey, with λ_{max} at about 565 and 530 mμ.

Similar experiments with human foveas yielded very nearly the same results. The results of one such experiment are shown in Fig 6. It involves the same procedures as were used in Fig 3. As in the monkey, differential bleaching with deep red light revealed a first pigment with λ_{max} at about 565 mμ, and a high absorption at 625 mμ, whereas the last pigment to bleach had λ_{max} about 535 mμ and very little absorption above 625 mμ. We assume again, therefore, that the red-sensitive pigment accounts completely for the total difference spectrum above 625 mμ, and makes its spectrum coincide with the total above this wave-length. On subtracting the spectrum of the red-sensitive pigment from the total, we obtain the curve shown as a broken line in Fig 6 (1–2). This is maximal at about 530 mμ. The last spectrum measured in the course of bleaching, as already said, is maximal at about 535 mμ. Both curves are reasonably close together in shape and position, and we take them—particularly the directly measured spectrum—to represent the difference spectrum of the green-sensitive pigment.

The human fovea, like that of the monkey, appears to contain considerably more of the red-sensitive than of the green-sensitive pigment. The proportions shown in Fig 7 are about 2 : 1. This is almost exactly the ratio that Rushton has reported finding between what he calls erythrolabe and chlorolabe in the human fovea[5].

The results of differential bleaching in human and monkey foveas are summarized in Fig. 7. In this figure all curves have been brought to the same arbitrary height to facilitate comparison. The red-sensitive pigments of human and monkey foveas yield virtually identical difference spectra, maximal at about 565 mμ. Small differences are found, however, in the difference spectra of the green-sensitive pigments, the human pigment lying at about 535 mμ, the averaged monkey curves at about 527 mμ. It is possible that the monkey spectrum is pulled toward shorter wave-lengths by the presence of small amounts of rhodopsin, owing to contamination of

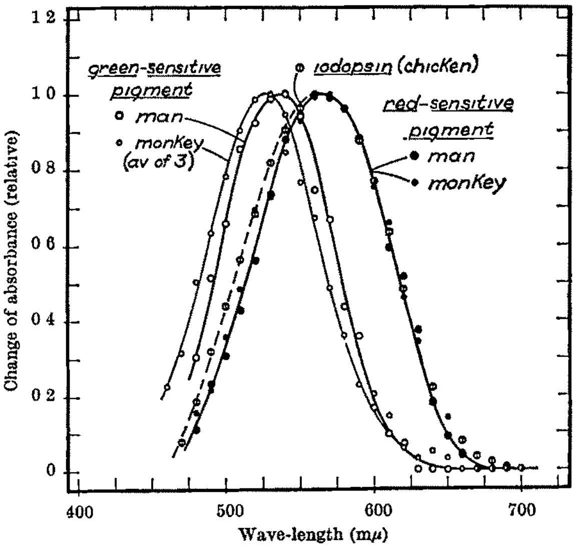

Fig 7. Difference spectra of photosensitive pigments of the central foveas of man and the rhesus monkey, brought arbitrarily to the same height for comparison. The red-sensitive pigments of human and monkey foveas are essentially identical, with λ_{max} about 565 mμ. Their difference spectra correspond closely with that of chicken iodopsin in aqueous solution, shown here with barred circles and a broken line. The difference spectrum of the human green-sensitive pigment is maximal at about 535 mμ. That of the monkey lies at slightly shorter wave-lengths (λ_{max} about 527 mμ), perhaps owing to the inclusion of a few rods and hence a small amount of rhodopsin in the measurement. The rod-free area of the monkey fovea is stated to be only 0.2 mm in diameter, the same size therefore as the area of retina measured in these experiments. The human rod-free area is about 0.5 mm in diameter, so making it easier to avoid the presence of rods in the field.

the field of measurement with a few rods. Polyak gives the diameter of the rod-free area in rhesus monkeys as 0.2 mm. If this is a reliable figure, our field of measurement should have completely filled this area, and the inclusion of a few rods in the field would have been unavoidable.

The experiments on differential bleaching, having begun with deep red light, always ended by exposing the retina to light of relatively short wave-lengths, that is, in the orange and yellow. Sometimes such light produced no further measurable bleaching. At other times it induced a very small further bleaching maximal in the neighbourhood of 440 mμ. Possibly this was due to the presence of a very small amount of a blue-sensitive pigment. We do not, however, regard our observations on this point as reliable. They were made under great difficulty since, as already noted, this region of the spectrum is very strongly absorbed by the macular pigmentation, and this is also the region in which the isomerization of retinaldehyde would yield a difference spectrum. Even if a blue-sensitive visual pigment were present in these foveas, bleaching it to retinal, which absorbs over the same region, should yield a highly distorted difference spectrum, lying further toward the red than the true absorption spectrum of the pigment.

Regeneration of cone pigments. Several times we have attempted to regenerate cone pigments in completely bleached human foveas. The cover slip of the microcell was lifted off, a droplet containing 4 μgm of 11-*cis* retinal in ethanol was stirred on its surface with 10 μl of glycerol-Ringer, and it was laid back on the retina. The tissue was then repositioned in the spectrophotometer and tested by differential bleaching with red lights as described previously. In a few such experiments enough cone pigment had regenerated to yield reasonably reliable difference spectra. The regenerated pigments never totalled more than about 0.25–0.5 of those present originally, so that no high accuracy could be achieved in such measurements, but the results showed clearly that both the red- and green-sensitive pigments regenerated. Also on re-bleaching these pigments complete difference spectra were obtained, showing clearly the emergence of retinal as a product of bleaching.

The observation that in experimental human vitamin A-deficiency cone vision deteriorates in parallel with rod vision, and that both are repaired simultaneously on administration of vitamin A, led to the conclusion some years ago that some or all of the human cone pigments, like those of the rods, are derived from vitamin A (now 'retinol')[17]. This is now demonstrated directly for two of the human colour vision pigments, together with the assurance that both pigments possess 11-*cis* retinal as chromophore. It seems probable that the human colour vision pigments are formed by joining this single chromophore to a variety of different opsins.

The red- and green-sensitive pigments of primate foveas appear from our measurements to lie at somewhat shorter wave-lengths than has commonly been supposed. We find the $\lambda_{\max}$ of the difference spectrum of the red-sensitive pigment to lie at about 565 mμ in both man and monkey, and the green-sensitive pigment to lie at about 535 mμ in man and perhaps as high—surely above 527 mμ—in the monkey. We take these difference spectra to be equivalent to true absorption spectra at wave-lengths longer than about 510 mμ, where the retinal produced by bleaching these pigments ceases to absorb appreciably.

In the case of the green-sensitive pigment the disparity with other measurements is small, perhaps negligible. Stiles's estimate of the spectral sensitivity of 'green'-cones finds it maximal at about 540 mμ[2], and Rushton gives the same value to the $\lambda_{\max}$ of the difference spectrum of the associated pigment, measured in protanopes[5]. In fact, however, Rushton's measurements have sufficient spread to agree as well with $\lambda_{\max}$ 535 as 540 mμ, so there is no clear disparity between his measurements and ours.

The red-sensitive pigment, however, raises a genuine issue, though here the disparity with data is sometimes less than with their descriptions in the literature. Stiles's original estimate of the spectral sensitivity of 'red'-cones, as also Rushton's estimate of the difference spectrum of the associated pigment, placed $\lambda_{\max}$ at about 590 mμ. Since his first measurements on his own eye, however, Stiles, working with other subjects and more varied procedures, has described a 'red'-cone mechanism, π_5, with a peculiarly broad maximum to which he assigns the value 575 mμ, not far therefore from that of our red-sensitive pigment[16]. It should be noted, therefore, that Rushton attaches little accuracy to his measurements on the red-sensitive pigment (see his discussion in ref. 19, 278). Having originally described its difference spectrum as near 590 mμ, he has recently published another such difference spectrum with $\lambda_{\max}$ near 570 mμ[20], and has also measured an action spectrum for its bleaching, with $\lambda_{\max}$ about 560 mμ (personal communication). At least some of Rushton's measurements on the red-sensitive pigment therefore are not inconsistent with ours. Weale, using methods comparable with those of Rushton, describes two human cone pigments with difference spectra which he says are maximal at about 540 and 600 mμ[21], his published measurements on the latter pigment, however, seem to us to display maxima well below 600 mμ, near 570 mμ.

It should be added that in the course of these experiments we tried hard to get the red-sensitive pigment to display a longer $\lambda_{\max}$ than 565 mμ, but without success. As already said, the first fraction of this pigment to bleach at the longest wave-lengths that were effective possessed $\lambda_{\max}$ about 565 mμ.

Fig. 7 shows that the difference spectrum of this red-sensitive pigment of primate foveas lies very close to that of chicken iodopsin in aqueous solution[22]. Indeed this pigment is iodopsin, though in this special position as one of a trio of colour vision pigments there may be an advantage in naming it accordingly. Among various sets of terms we have lately been offered for the colour vision pigments, we think those proposed by Rushton to be the most apt and beautiful. We should be glad therefore to speak of iodopsin in this special connexion as 'erythrolabe', if Rushton will accept a $\lambda_{\max}$ near 565 mμ in place of the $\lambda_{\max}$ of 590 mμ that he has attached to the latter term. Similarly our green-sensitive pigment might be called 'chlorolabe'. The difference spectrum of the blue-sensitive pigment 'cyanolabe' has yet to be measured, though we already have approximations to the associated spectral sensitivity function, maximal at about 440 mμ[2,3], undoubtedly distorted somewhat by the filtering action of the macular pigmentation.

From the point of view of the chemistry of visual pigments, it is significant that iodopsin and the red-sensitive pigment of primate foveas lie farthest toward the red of all known visual pigments having retinal (retinene$_1$) as chromophore. It is difficult enough to attempt to explain how coupling retinal, with $\lambda_{\max}$ about 380 mμ, to opsin can achieve as long a $\lambda_{\max}$ as 565 mμ, and there is some relief in knowing that there is no need at present to go further.

Another feature of our measurements of some interest is the ratio of densities of the red- and green-sensitive pigments, which we find in the human fovea to be about 2:1. This agrees well with Rushton's estimate, but in view of uncertainties surrounding his measurements of the red-sensitive pigment, that still may be held to leave the issue in doubt. It might be supposed that previous exposures to light could have displaced this ratio somewhat in our human eyes. It might be objected also that the red light used in preparing and mounting our retinas might have differentially bleached some of the red-sensitive pigment, but in that case its ratio to the green-sensitive pigment in the normal fovea should be even higher than we find.

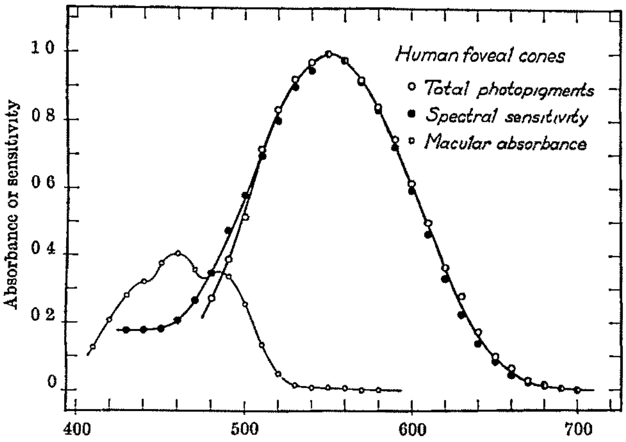

Fig 8 Comparison between the difference spectrum of the total photopigments of the human central fovea (average of 5 foveas) and the spectral sensitivity of human foveal vision, measured as though at the level of the cone outer segments To obtain the latter function, a group of representative measurements of the photopic luminosity curve was averaged, converted to a quantum basis, and corrected for the transmission of the ocular media according to Ludvigh and McCarthy, and the macular pigmentation, measured directly in the present experiments The spectrum of a human macula, as shown, was given the maximal extinction 0 405 at 460 mμ, corresponding to about 60 per cent absorption, probably close to the average in human observers The close correspondence between the difference spectrum of the total foveal photopigments and the spectral sensitivity of foveal vision above 500 mμ offers some assurance that our difference spectra of the red- and green-sensitive pigments, which, as shown in Fig 6, add up to yield the total difference spectrum, represent correctly at wave-lengths above 510 mμ the absorption spectra and proportions of these pigments in the living human eye

Some assurance with regard to this ratio and other characteristics of our measurements can be gained by comparing the difference spectrum associated with total bleaching of the fovea in our experiments with the spectral sensitivity of human foveal vision Such a comparison is shown in Fig 8

The spectral sensitivity of the human fovea is described by the well-known photopic luminosity function of the human eye This is of such great importance industrially and otherwise as to have been measured often and well In the present instance we have combined some of the most representative of such measurements to yield a composite function of high reliability[23]. This, however, represents the foveal spectral sensitivity in terms of energies incident on the cornea, whereas for comparison with the visual pigments one needs the foveal sensitivity in terms of numbers of quanta incident on the outer segments of the cones Apart from quantizing the measurements, therefore, we have corrected them for the filtering action of ocular structures light absorbed or scattered in passing through the ocular tissues as estimated by Ludvigh and McCarthy[24], and absorption by the macular pigmentation We have measured the latter repeatedly in the course of the present investigation (cf Fig 8), and will describe it in more detail elsewhere For the present computation we have assumed a macular pigment density corresponding to 60 per cent absorption at 460 mμ, close to the average value observed earlier in human subjects[10]

The spectral sensitivity of foveal cones, quantized and corrected for ocular transmission so as to be applicable at the receptor surface, is compared in Fig 8 with the average difference spectrum obtained from wholly bleaching five human foveas The two functions are in good agreement at wave-lengths longer than 510 mμ, where the difference spectrum approximates a true absorption spectrum Below 510 mμ, the spectral sensitivity curve probably continues to represent reasonably accurately the absorption spectrum of the total foveal photopigments

This comparison to a degree constitutes a searching test of the reliability of our measurements Figs 5 and 6 show that the total difference spectrum of human and monkey foveas is well accounted for by the individual difference spectra of the red- and green-sensitive pigments in the proportions shown in these figures. It is difficult to see how the total difference spectrum of the human fovea would agree with its spectral sensitivity as shown in Fig 8, were it not true that our difference spectra of the red- and green-sensitive pigments are equivalent at long wave-lengths, as we have assumed, to true absorption spectra, and that they have about the same positions and proportions in the living eye as we have found in excised retinas

This comparison bears also on a final consideration It has long been recognized that, though the spectral sensitivity of red-blind subjects (protanopes) is abnormally low in the red, and is often assumed to approximate the spectral sensitivity of the green-receptor, the spectral sensitivity of deuteranopes, which might conversely be expected to approximate that of the red-receptor, in fact lies close to that of normal trichromatic observers For this reason Konig[25] (cf also Judd[26]) supposed that the spectral sensitivity of the red-receptor must resemble the total luminosity function, and must account almost entirely for the photopic luminosity

Actually the luminosity curve of deuteranopes does depart somewhat from the normal function, displaying a measurable depression of sensitivity in the green and blue and a small displacement of maximum toward the red[27] All these relationships are made easier to understand by our observations, on one hand that the red-sensitive receptor has its peak of absorption and hence presumably its peak of sensitivity at as low a wave-length as 565 mμ, hence not far from the normal photopic luminosity maximum, and that the red-sensitive pigment dominates foveal vision

This work was supported in part by the U S National Science Foundation and the Office of Naval Research We thank the Boston Eye Bank for gifts of human eyes not needed for corneal transplantation, and Prof Frederick Hisaw of this Department for gifts of monkey eyes

SEIZURES INDUCED BY INTRAVENTRICULAR SODIUM

By PROF GILBERT H. GLASER and GEORGE WOLF

Section of Neurology, Department of Medicine, Yale University School of Medicine,
New Haven, Conn

THE activity of cerebral neurones as characterized by membrane excitability and impulse conduction is directly dependent on the metabolic environment A critical factor is the maintenance of membrane resting potential by the distribution of sodium, mainly extraneuronally, and potassium, mainly intraneuronally Shifts of this ionic balance have been found associated with cerebral seizures, the repetitive discharging of hyperexcitable neurones. There is evidence that during and probably prior to a seizure discharge there is a decrease in the ratio of concentrations of extraneuronal to intraneuronal sodium[1,2] mainly due to an increase in the latter

The technique developed by Feldberg and Sherwood[3] of intraventricular injections in otherwise intact animals has offered an approach to this problem on a neurophysiological and behavioural level During the past ten years many drugs and certain ions have been so administered[4-6] It was found that intraventricular calcium induced a peculiar ataxia, then sleep-like state, potassium administration caused seizures with autonomic effects and circling movements, but never drinking[7] Sodium was given only as 'control', in isotonic solution, and no significant effects were noted However, Sawyer and Gernandt[8] described 'saline-induced seizures', induced by intraventricular or intracarotid hypertonic saline, in non-behavioural, acute electroencephalographic investigations in curarized rabbits The seizure activity was confined to the amygdala and hippocampus and was not produced by isotonic saline, or hypertonic glucose or urea Miller[9] has reported drinking behaviour in cats produced by intraventricular injections of hypertonic sodium chloride

The present work represents an attempt to investigate the seizure phenomena induced by increasing the sodium concentration of the intraventricular fluid by the administration of hypertonic saline, both behaviourally and by subcortical and cortical electroencephalographic recording Experiments were performed in twelve cats with chronically implanted intraventricular cannulæ and stainless steel electrodes placed stereotaxically in cerebral cortex, amygdala, hippocampus, caudate nucleus, thalamus, central grey and hypothalamus The animals were examined in a recording box in which they could move about freely while being observed through a one-way vision window After a series of experiments the brain from the animal was fixed by perfusion, the electrode and

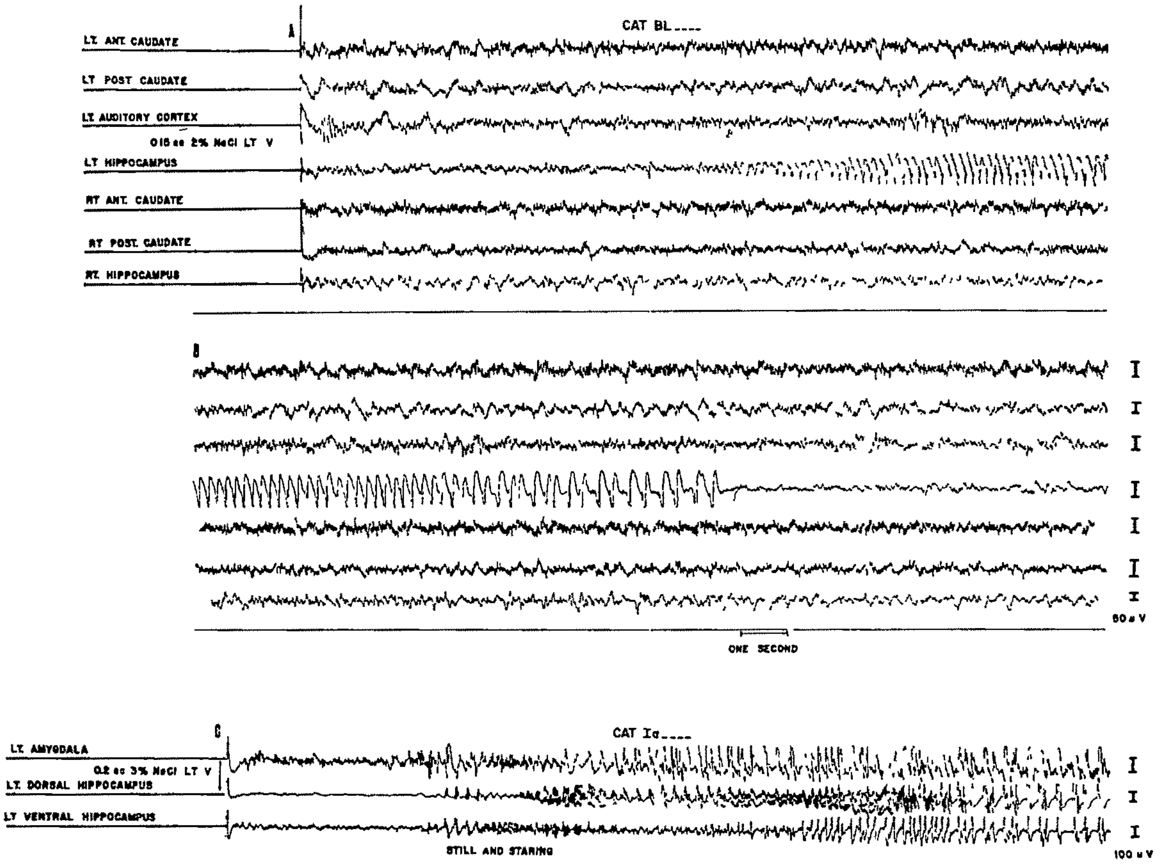

Fig 1 *A*, Electrographic seizure activity developing in left hippocampus and remaining localized therein following injection of 2 per cent sodium chloride (0 15 c c) into left lateral ventricle *B*, Continuation of discharge in left hippocampus Total duration 21 sec *C*, Electrographic seizure activity developing in left amygdala and hippocampus following injection of 3 per cent sodium chloride (0 2 c c) into left lateral ventricle During this period of discharge, which lasted for 32 sec (only the initial portion is shown here), the cat remained transfixed in a still position and stared ahead, occasionally with licking movements

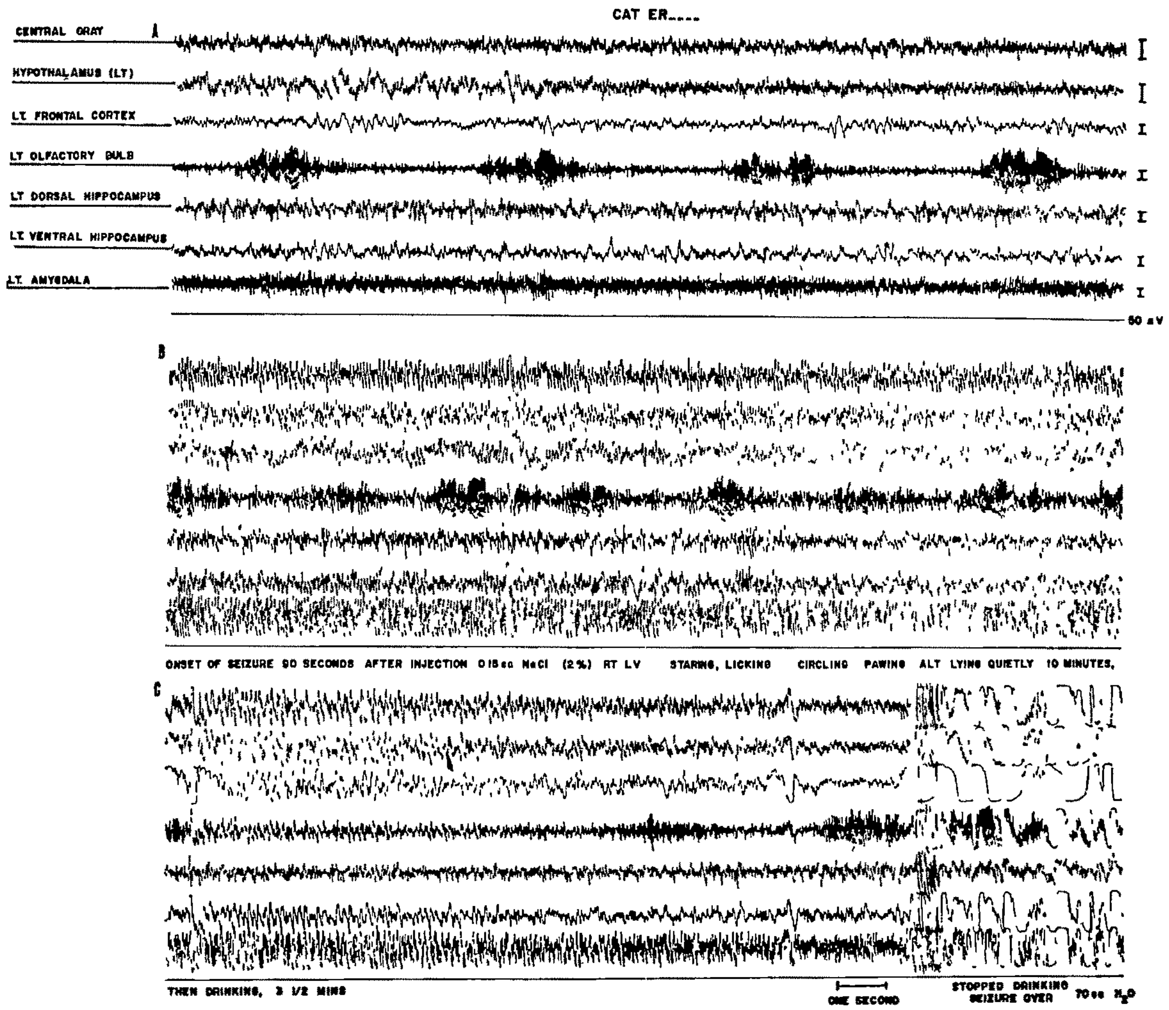

Fig 2 *A*, Control electroencephalographic recording from subcortical and cortical structures *B*, Recording during seizure induced by injection of 2 per cent sodium chloride (0 15 c c) into right lateral ventricle For a 10-min period the cat alternately circled, pawed, stared, licked lips or lay quietly *C*, Recording during the terminal 3 5-min phase of the seizure while the animal was drinking 70 c c of water

cannula placements were confirmed histologically and the tissues were evaluated for pathological changes

Control experiments included the intraventricular administration of isotonic sodium chloride solution and hypertonic mannitol and sorbitol, of the same osmolarity as the salt solutions None of these injections induced any significant behavioural or electrographic changes

The hypertonic sodium chloride injections were of 2 or 3 per cent solution in amounts of 0 15 c c or 0 2 c c These intraventricular administrations of hypertonic saline induced varying seizure phenomena in the same and different animals Seizure discharges occasionally appeared isolated to the hippocampus ipsilateral to the injection, beginning within 10 sec and lasting up to 30 sec, and were not associated with behavioural alterations At times staring and arrest of movement appeared briefly, associated with discharges involving hippocampus and amygdala (Fig 1).

Generalized seizure activity also occurred (Fig 2), probably originating in the hippocampus, then involving other subcortical structures amygdala, caudate, thalamus, hypothalamus and central grey Spread to cortex was minimal The electrographic discharges were associated with complex behavioural seizures lasting 10 or more min with staring, circling, drooling and finally heavy drinking of water

In some experiments with implantations of numerous recording electrodes in one hemisphere the ventricular cannula was placed into the opposite lateral ventricle (Fig 2) The electrographic effects of contralateral injections had a latency which varied from 10 sec to 3 min, although behavioural changes appeared within 30–60 sec In one experiment, a prolonged depression and desynchronization of caudate activity followed by slow-wave discharges occurred in the absence of changes elsewhere In another experiment a seizure discharge rapidly spread to auditory cortex and remained there for more than 1 min without any significant behavioural change The repetition of intraventricular injections of hypertonic sodium chloride usually produced a temporary refractory state Seizures could be induced two or three times in a series of experiments, then no longer for several days or weeks No significant increases in intraventricular pressure were observed There were no discernible tissue lesions other than those usually produced by implanted electrodes and cannulæ

The intraventricular injections in these experiments increased the total intraventricular fluid volume by only at most 4 per cent, which is not regarded to be significant It is regarded that the seizure phenomena observed were in some way related to the increase in the sodium concentration of the intraventricular fluid and not a change in tissue hydration since the effects were not produced by hypertonic sugar solutions The amount of sodium added by the hypertonic injection is in the range of 20–25 m mole/l , an increase of about 17 per cent This increase would occur initially, at probably a higher level, before diffusion, in the lateral ventricular region, which occupies an extensive area bathing the hippocampus, the region usually initially developing seizure discharges, which then spread to amygdala and related structures These limbic masses are known to have relatively low seizure thresholds[10] Behaviourally, the induced phenomena resembled psychomotor-temporal lobe seizures, with certain aspects of caudate and hypothalamic involvement as well

It may be postulated, therefore, that sodium diffusion occurs across the ependymal wall into glia and neurones, eventually increasing intraneuronal sodium concentration and producing thereby a state of oscillating depolarization, hyper-excitability and seizures[1] Since an increase in intraventricular potassium also induces seizures, the reciprocal relationships between these cations need further evaluation That a certain specificity of effect exists, possibly in relationship to ventricular wall osmoreceptors or specific cationic sensitive cells, is indicated by the drinking behaviour produced by sodium but not by potassium injections Further study is required of the actual distribution of these ions into cerebral tissues following intraventricular administration and the time factors involved

Of interest in relation to the work recorded here is the production of increased spinal reflex excitability by intracarotid injections of hypertonic saline, presumably mediated by supraspinal mechanisms[11]

A conclusion that a shift of sodium alone is of primary responsibility in the induction of an epileptic state in neurones would be quite unwarranted However, these experiments and the related data from the literature are quite suggestive of a pattern that does involve a major intraneuronal shift of sodium, in the important regulation of membrane stability There probably is a complex interplay between sodium, potassium, cerebral transmitters (as acetylcholine) and amino-acids[1]

PROTECTIVE EFFECT OF DEEP-BODY HYPOTHERMIA ON X-RAY-INDUCED MITOTIC ABERRATIONS OF REGENERATING RAT LIVER

By DR. M. J. ASHWOOD-SMITH* and DR. G. F LEONG

U.S. Naval Radiological Defense Laboratory,
San Francisco, California

EARLIER investigations have demonstrated that in adult rats exposed to X-rays a high incidence of abnormal mitotic figures occurs after partial resection of hepatic tissue[1–3] This preponderance of mitotic aberrations which can be clearly identified in the anaphase and telophase stages of division has been shown to persist undiminished for long periods of time[2–4] and also after multiple episodes of induced cell proliferation[3] (repetitive partial hepatectomies) This radiation damage to the mitotic apparatus of the parenchymal cells apparently remains dormant for months after irradiation exposure without any detectable alterations in liver function[5] However, when the previously irradiated cells are stimulated to divide by partial hepatectomy, the mitotic aberrations are increased 5–7-fold Hornsey[6] has demonstrated that there is a 2 8 dose reduction factor in terms of LD_{50} when mice are irradiated under conditions of deep-body hypothermia (+1° C) Bone marrow and lymphoid tissue of mice irradiated under hypothermic conditions are protected, this protection is probably associated with the low oxygen tensions present in these tissues during irradiation[7] It is well known that radiation-induced chromosome aberrations both in plant and animal cells are reduced when the irradiation occurs under anoxic or relatively anoxic conditions[8] It is the purpose of this article to describe the protective effect of hypothermia against radiation injury with respect to growth rate, regenerative capacity of the liver, and mitotic aberrations of parenchymal cells

Rats (male Sprague–Dawley, *NRDL* strain) were divided into four groups of 10 rats per group One group acted as controls, the second group was irradiated at normal body temperature, the third group was irradiated when the rectal temperatures of the rats had been reduced to about 1° C The last group was rendered hypothermic but not irradiated All irradiations were carried out when the animals were four weeks old and the partial hepatectomies to stimulate liver regeneration were performed eleven weeks later Water and food ('Purina' laboratory chow) were supplied *ad libitum*

The closed jar method of Giaja and Andjus[9] was used to render rats hypothermic When the rectal temperature reached about 17° C and respiration ceased, the rats were taken out of the bottles and packed in ice After another 20 min the rectal temperature had fallen to about 1° C, at which temperature the rats were either irradiated or sham irradiated Resuscitation of the hypothermic rats by the technique of Andjus and Smith[10] was started immediately after irradiation These animals usually recovered within 40 min after removal from the ice bath Rats were exposed to a single whole body dose of 450-rads X-rays (250 kVp , 15 m amp , filter 0 5 mm copper and 1 mm aluminium, half-value layer 1 4 mm copper, *TSD* 40 in , dose rate 50 rads/min) The non-hypothermic rats were irradiated in 'Perspex' restrainers and received the same total dose and dose rates as the hypothermic animals which were packed in ice (radiation dose corrected for scatter)

To minimize possible variations due to the diurnal cycle of the rat[11] surgery was scheduled so that all animals would be killed in the morning hours The procedure of Higgins and Anderson[12] was used for the partial hepatectomy All animals were subjected to a single partial hepatectomy eleven weeks after they had been subjected to either hypothermia, irradiation, or a combination of both A control group which received no treatment was similarly partially hepatectomized Animals were killed by exsanguination 36 h after partial hepatectomy Histological specimens were taken from each lobe of every liver and the tissue fixed in Tellyesniczky's solution (ethyl

alcohol, glacial acetic acid, and formalin) for 8–12 h, dehydrated, embedded in paraffin, sectioned at 5μ, and stained with Harris's hæmatoxylin and eosin.

Mitotic aberrations and mitotic indices were determined and counted under oil immersion (×800). Although abnormalities were observed in all stages of mitoses, only those occurring during anaphase and telophase were evaluated for abnormalities from every liver. Results of counts are expressed as the ratio of abnormal figures to the total number of figures viewed.

Mitotic index is expressed as the number of mitoses per one thousand parenchymal cells counted. All mitoses from late prophase to late telophase in one hundred fields of each slide were counted, but only the parenchymal cells in every fifth field were enumerated. The reliability of this counting procedure was tested by counting all mitoses and parenchymal cells in one hundred consecutive fields on several slides from each group. With these procedures a minimum of four thousand to five thousand cells per slide was viewed.

A comparison of the body-weight changes in the four groups of animals is shown in Fig. 1. These results demonstrate that hypothermia alone or hypothermia and X-rays retard body growth of animals. A single dose of irradiation has a greater effect on the growth rate of these animals as compared with hypothermia alone. However, hypothermia all but abolished the detrimental effect of X-irradiation on the future growth of these animals.

The mitotic indices of the regenerating rat liver in all four groups are shown in Fig. 2. The mitotic index of the control group was significantly higher than that of the X-ray group, 52 mitoses per one thousand parenchymal cells as compared with 32 mitoses per one thousand parenchymal cells ($P < 0{\cdot}01$). At 36 h after partial hepatectomy no detectable differences in mitotic indices could be distinguished between hypothermic and control animals. The animals subjected to both hypothermia and X-rays did not appear to be significantly different as compared with hypothermia alone or with the control group. However, there appears to be a suggestion of a slight protective effect of the hypothermia against the X-rays when these two groups are compared ($P = 0{\cdot}05 - 0{\cdot}1$).

The percentage (± S.D.) abnormal mitoses occurring in all four groups at 36 h after partial hepatectomy is shown in Fig. 3. The control values are 7·1 per cent ± 1·7 whereas the values for the X-irradiated animals are 36·6 per cent ± 4·6. Animals subjected to hypothermia alone yielded values of approximately 9·1 per cent ± 2·5 and the animals subjected to both X-ray and hypothermia yielded values of 9·4 per cent ± 2·2. These results demonstrate that hypothermia alone does not have any effect on the incidence of abnormal mitoses, whereas the damaging effects of X-rays are completely abolished by concomitant hypothermic conditions.

There have been numerous papers published on the effect of oxygen in enhancing radiation-induced chromosome damage since the original observations of Thoday and Read[13]. The effect of temperature in modifying chromosome damage has been investigated by several workers. Sax and Enzmann[14] found that the frequency of X-ray-induced aberrations in *Tradescantia* microspores increased with decreasing irradiation temperature and that the yield of aberrations was roughly four times greater at 3° C than at 36° C. The solubility of oxygen increases with decreasing temperatures and it is quite possible that the greater number of aberrations seen at lower temperatures may have been associated, in part, with the greater number of oxygen atoms available for combination with the free radicals produced from the radiolysis of water.

Recent work has suggested that the high number of aberrations seen after irradiation at temperatures just above 0° C does not occur when oxygen is absent during irradiation. Baker and Sgourakis[15] have shown that the number of recessive lethals induced in *Drosophila* by irradiation was temperature-dependent only in the presence of oxygen, if irradiation was carried out in the presence of nitrogen then no temperature effect could be detected. A slight increase of the chromosome aberrations in *Tradescantia* with decreasing temperature has been reported by Giles[16] when the partial pressure of oxygen was kept constant. More recent work by Beatty and Beatty[17] has demonstrated that the frequency of aberrations increases with increasing temperature when microspores are irradiated under anoxic condition. A

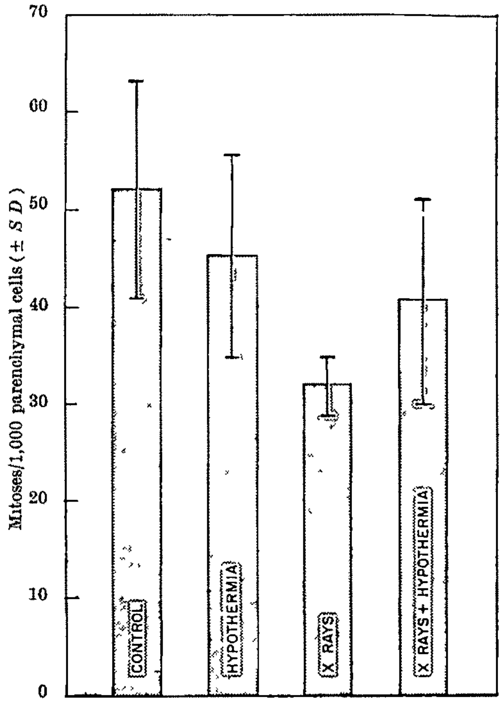

Fig. 2. Effect of hypothermia and X-rays on the mitotic index of regenerating rat liver

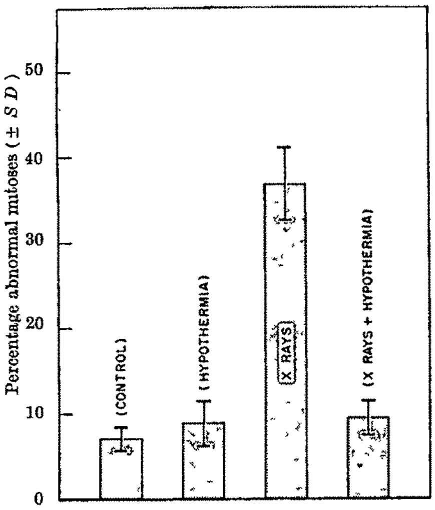

Fig 3 Protective effect of hypothermia on radiation-induced mitotic aberrations in regenerating rat liver

small decrease in the number of aberrations was noted when the temperature was lowered and irradiation performed in the presence of oxygen A slight increase in the number of aberrations is seen when Erhlich ascites tumour cells are irradiated under either anoxic or normal conditions as the irradiation temperature increases[18]

There have been several attempts to prevent radiation-induced chromosome damage by pretreatment of cells with chemicals A significant reduction in the number of aberrations induced by X-rays in *Tradescantia* has been reported by Mikaelson[19] provided that the tissues were pretreated with glutathione or cysteine Sodium hydrosulphite and BAL are also effective in reducing chromosome damage[20,21] However, the extent of the reduction was no greater than would have been expected to have occurred from the decreased oxygen tension produced by these two reducing chemicals The same degree of protection was achieved by irradiation under anoxic conditions

Weiss[7,22] has shown that oxygen tensions are very low in the tissues of mice subjected to hypothermia (rectal temperatures in the regions of +1° C) This amount of anoxia was sufficient to give considerable protection to the testes, bone marrow and lymphoid tissues of mice irradiated while hypothermic It is not surprising to find, in these present experiments, that hypothermia has protected rats from the body-weight changes induced by radiation and there is a suggestion that the induction of mitotic delay by radiation has also been slightly affected by hypothermia, however, this latter effect is not statistically significant The dramatic reduction afforded by hypothermia against radiation-induced mitotic aberrations was unexpected A reduction of 2- or 3-fold in the number of the aberrations would, perhaps, not have been unexpected in view of the probable anoxic state of the liver cells The consensus of opinion with regard to chromosome aberrations and temperature is that under anoxic conditions temperature *per se* has but a slight effect on the frequency of radiation-induced aberrations A large number of aberrations would probably have resulted during the low-temperature irradiations had oxygen tensions been within normal physiological limits There is the possibility of repair occurring during the long interval between X-ray exposure and cell proliferation and that this repair may be further enhanced by hypothermia However, this explanation does not seem likely since others[2,4] have shown that these abnormal mitotic figures do not diminish over long periods of time Although the present results do not allow distinction between temperature effects and oxygen effects it would seem unlikely that low temperature is the predominant protective factor The most reasonable suggestion seems to be that in liver parenchymal cells in interphase most of the observable mitotic aberrations induced by X-rays are oxygen-dependent and can be prevented by deep-body hypothermia

EFFECT OF THE INTRODUCTION OF AN IRRELEVANT STIMULUS ON RUNWAY PERFORMANCE OF THE HIPPOCAMPECTOMIZED RAT

By WARREN O. WICKELGREN* and PROF R. L. ISAACSON

Department of Psychology, University of Michigan, Ann Arbor

IT is now evident that rats with hippocampal destruction have difficulty in terminating certain kinds of responses This is evidenced by greater resistance to extinction of such animals in a shuttlebox avoidance problem[1] and in the straight runway[2] Furthermore, hippocampectomized animals have difficulty in forming a passive avoidance response[3], and one interpretation of this observation is that these animals have an inability to stop making the dominant response in this situation

In experiments testing the ability to make passive avoidance responses, however, the animal's approach response is penalized by a noxious stimulus, usually an electrical shock The question arises as to the effects of introducing an affectively neutral, and task-irrelevant, stimulus while animals with hippocampal lesions are performing a well-established response Would the introduction of this kind of stimulus interrupt the ongoing behaviour patterns of the hippocampectomized animals

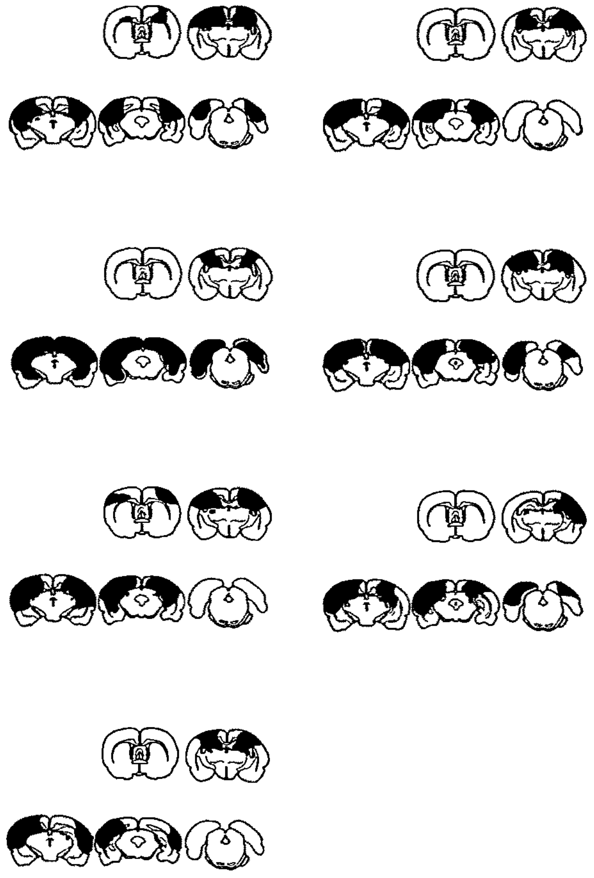

Fig 1 Diagrams of the extent of damage of all animals receiving hippocampal lesions. Thalamic gliosis indicated by stippled areas

to the same extent it would in control animals? In this experiment we attempted to assay the effects of adding an irrelevant stimulus without noxious qualities to a simple, well-established response in hippocampally ablated animals and in two control groups One control group received extensive neocortical damage and the other control group received only sham operations

The subjects were 19 male hooded rats of the Sprague–Dawley strain which were approximately 120 days old at the time of operation Seven animals received bilateral hippocampal lesions, 5 received neocortical lesions, and 7 received sham operations in which no brain tissue was damaged

The operative procedure was similar to that previously described except that the animals were not held in a stereotaxic instrument[1] The sham operated animals received all the surgical procedures used with the brain-lesioned groups except that no brain tissue was damaged After the surgery, the animals were kept in group cages for 2 days and during these post-operative days received 'Tetracyn' (tetracycline) in their drinking water Then, the animals were placed in individual cages for the remainder of the experiment

The apparatus was a straight-alley runway constructed of ¼-in plywood, painted black, with internal dimensions 54 in × 4 in , and 6 in high One guillotine door was located 11 in down the runway, providing a startbox, and a second door was located 21 in from the end of the runway and was used to prevent retracing Response latencies were measured from the raising of the startbox door and were stopped when the animal crossed a photoelectric cell unit located 5 in down the runway from the start door

Thirty days after undergoing surgery, all animals were placed on a deprivation schedule in which they were fed 15 g of 'Purina' laboratory chow, which kept all the animals at about 85 per cent normal body-weight Each subject was weighed and handled for about 5 min before being fed its daily ration Preliminary training was begun 9 days after the beginning of the deprivation period and consisted of giving each animal a 5-min period in which to explore the runway on each of two successive days The time taken to traverse the runway was recorded with no attempt made to prevent retracing After each daily preliminary trial, the subjects were placed in a small box which contained the food cup with two 45-mg Noyes Co food pellets and several drops of water The animal remained there until it had eaten the pellets and was then removed while two other pellets and drops of water were placed in the food cup This procedure was continued until every animal had been placed in the box and eaten the pellets 5 times

Acquisition consisted of 10 trials a day for 7 days with a reward of 2 food pellets at the end of the runway on each trial Each animal was allowed 10 sec to eat the pellets and was then replaced in its holding cage while the latency and running times were recorded The inter-trial interval varied between 30 and 45 sec A small fan in the experimental room emitted a constant noise and was used to mask other sounds All animals were run between 7 and 11 p m in two squads

On the eighth and ninth days of training, wooden strips on which sandpaper had been stapled were placed over the regular floor of the runway The startbox flooring remained the same, so that when the startbox door was opened there was a slight step up to the coarse, lighter-coloured flooring Ten rewarded trials were given on the days on which the sandpaper floors were added

After the experiment, the animals were killed and intracardially perfused with 10 per cent formalin The brains were removed, dehydrated, and embedded in paraffin Sections were cut at 21-μ intervals through the lesions Every tenth section was retained and stained with thionin Histological examination of the sections indicated that about 75 per cent of the hippocampal formation had been destroyed in most of the hippocampally ablated animals Minor injury to the thalamus was found occasionally In general, neocortical destruction was greater in the neodecorticate control group than in the hippocampally lesioned group as a result of our attempts to equate the total amount of brain tissue destroyed between the two

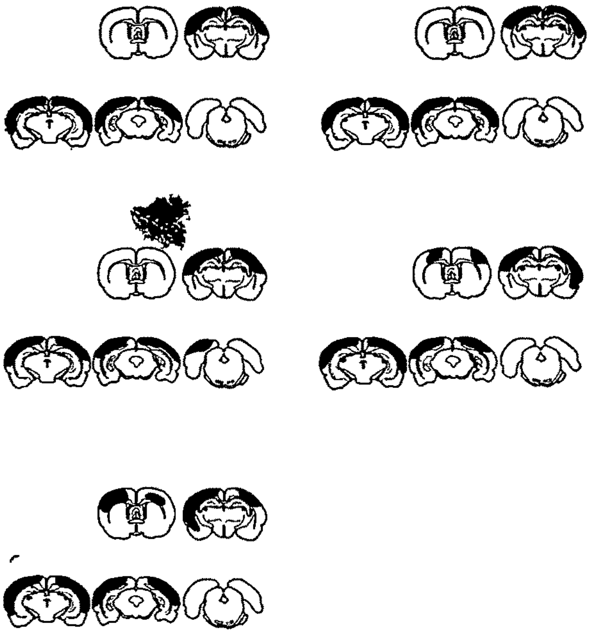

Fig 2 Diagrams of the extent of damage of all animals receiving neocortical lesions Thalamic gliosis indicated by stippled areas

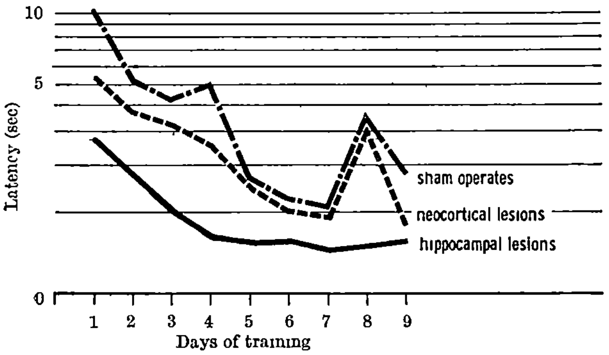

Fig. 3. Mean latency scores on the three groups of animals plotted on a logarithmic scale. Irrelevant stimuli were added to the runway on the trials given on days 8 and 9

brain-lesioned groups. In several hippocampectomized and neodecorticate animals gliosis was found in certain thalamic nuclei. The gliosis appeared to be a result of surgically induced infarction and was seen in the lateral and medial geniculate nuclei and to a much less extent the anterior and lateral nuclei. The degree of thalamic gliosis was found to be unrelated to the behavioural effects of the lesions. Figs. 1 and 2 present the extent of the lesions at 5 levels through the brains of the hippocampectomized and neodecorticated animals, determined by projecting the mounted brain sections on to standard drawings of a normal brain at that level.

The results of the experiment were clear cut. Because of the magnitude of the effect, it was felt that raw response latencies would best serve to illustrate the results.

Fig. 3 summarizes the results of the experiment in graphic form. The two control groups of animals showed a considerable increase in latencies when the irrelevant stimuli were introduced but the hippocampectomized animals did not reveal any discernible change. Due to the variability of the control groups, the differences between the groups during acquisition training do not reach significance at the 0.05-level, although the likelihood of such a consistently superior performance by the hippocampectomized rats over the first seven acquisition days occurring through chance alone is quite remote. Difference scores between the 7th acquisition day and the 1st day on which the irrelevant stimulus was presented (8th training day) for each animal yielded an F-ratio significant beyond the 0.05-level; t tests indicated a significant ($P < 0.02$) difference between hippocampal lesioned animals and those in the control groups on the 1st distraction day.

The results of this experiment fit in well with recent work in which hippocampally lesioned animals were found to perseverate an old response in the face of altered conditions. The hippocampally lesioned rats also seemed to acquire the response more rapidly than did the control groups and this agrees with other investigations in which hippocampal ablation facilitated certain kinds of learning[1].

These results extend our knowledge of the behaviour of hippocampectomized rats to show that the introduction of a novel but affectively neutral stimulus, which is irrelevant to the performance of the previously acquired running response, fails to inhibit running behaviour. Earlier reports had noted the diminution of effects of presentation of noxious stimuli in passive avoidance situations, and also a diminution of effects produced by stimuli which had been associated with noxious stimuli[4]. The explanation for this behavioural change is not unambiguous. These results would be expected on the bases of 'response inhibition theories' like those presented by McCleary and Kaada, which would suggest that animals with certain subcortical damages may notice and respond to changes in environmental stimuli, but cannot, because of the lesion, stop making the dominant response[5]. However, other types of explanations could account for our results. If the S's were merely deficient in abilities required to attend to, or orient toward, novel stimuli, this would be adequate to account for the present results. Along these lines, Lissak and Grastyan have reported evidence which links changes in the electrical activity of the hippocampus to periods when the animal is exhibiting the orienting reflex described by Pavlov[6]. It should also be mentioned that the functions of the orienting (investigatory) reflex are to cause the animal to orient toward the source of stimulus change and, at the same time, to inhibit conflicting response tendencies. Whether lesions in the hippocampus interfere with one or both of these behavioural functions remains to be established.

This work was supported in part by a grant from the office of the Surgeon General, U.S. Army (*DA-MD*-49-193-63-*G*75).

EFFECT OF ACTINOMYCIN D ON INTERFERON PRODUCTION BY 'ACTIVE' AND 'INACTIVE' CHIKUNGUNYA VIRUS IN CHICK CELLS

By Dr. G. E. GIFFORD* and Dr. E. HELLER†
National Institute for Medical Research, Mill Hill, London, N.W.7

HELLER[1] has examined the effect of actinomycin *D* on the growth of Chikungunya virus in chick cells and on production of interferon resulting from such infection. He found that actinomycin markedly enhanced the growth of the virus and that interferon production was inhibited. On the basis of his kinetic investigations it seemed likely that the inhibition of interferon production by actinomycin was responsible for the enhancement of virus growth. However, it was also possible that the enhanced virus growth occurring as a result of treatment with actinomycin may have been responsible for the inhibition of interferon production in a manner analogous to the 'inverse interference' phenomenon described by Lindenmann[2]. This could occur if the production of interferon and virus by the same cell were not compatible phenomena.

We have compared the effect of actinomycin *D* on interferon production by stock preparations of Chikun-

† Present address: Department of Preventive Medicine, Hebrew University-Hadassah Medical School, Jerusalem.

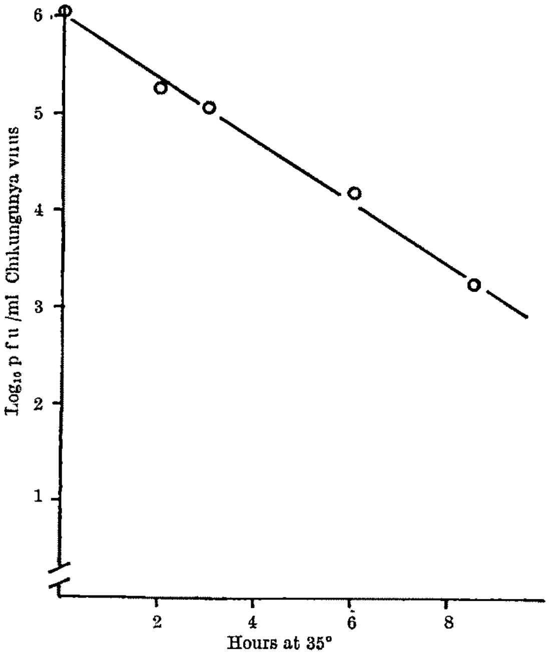

Fig 1 Rate of inactivation of Chikungunya virus at 35°

gunya virus and by preparations which have lost their plaque-forming ability as a result of incubation at 35° If the stimulation of virus growth by actinomycin was responsible for the inhibition of interferon production then actinomycin would have less inhibitory effect on interferon production by 'inactive' virus

Interferon and virus were assayed in chick cells infected with vaccinia virus by the method described by Lindenmann and Gifford[3] Chikungunya virus was assayed by a plaque technique on chick cells The medium used for interferon production consisted of Gey's balanced salt solution with 0 11 per cent sodium bicarbonate, 0 25 per cent lactalbumin hydrolysate, 0 1 per cent yeast extract, and 0 1 per cent proteose peptone Interferon-containing samples were heated at 65° for 30 min This procedure inactivated the infectivity of the virus and also its interfering ability (Heller, unpublished observations) Chikungunya virus was grown in the brains of new-born mice and vaccinia virus on the chlorioallantois of embryonated eggs Both viruses were stored in glass ampoules at – 60°

The rate of inactivation of the virus at 35° was investigated since this was the temperature utilized during adsorption of the virus on to chick cells A suspension of the virus was made in the described medium and placed at 35° At intervals, samples were removed and frozen at – 60° for plaque assay As seen in Fig 1, the virus was found to be rendered incapable of producing plaques at a rate of approximately 1 log$_{10}$ every 3 h

Chikungunya virus, incubated at 35° for 23 h, was tested for its ability to induce interferon in chick cells No plaque-forming virus was found in the inoculum, but good yields of interferon were obtained A comparison of this 'inactive' virus preparation with the stock preparation of Chikungunya virus was then made in the absence and presence of actinomycin *D* to determine if production of interferon would be inhibited Cells were treated with 0 06 μg/ml of actinomycin *D* for 4 h at 35° Medium was decanted and the cells washed with fresh medium Controls were treated in the same manner except that actinomycin was omitted Cells were then exposed to either the stock preparation or to the 'inactive' virus preparation of Chikungunya virus at the same dilution so that the number of physical virus particles was the same The cultures were incubated at 37° and after 24 h the media were collected, heated at 65° for 30 min, and assayed for interferon The results are shown in Table 1 Both preparations of virus induced the production of interferon, and actinomycin treatment inhibited interferon production almost completely in both cases The 'inactive' virus produced approximately 23 per cent more interferon than the 'active' preparation

Table 1 PRODUCTION OF INTERFERON BY 'ACTIVE' AND 'INACTIVE' CHIKUNGUNYA VIRUS AND ITS INHIBITION BY ACTINOMYCIN *D*

Nature of virus preparation*	Pretreatment with actinomycin †	Total PDD_{50} units interferon produced in 24 h ‡	Inhibition (%)
'Active'	—	312	—
,	+	18	94
'Inactive'	—	385	—
,,	+	13	97

* For details see text

† Actinomycin, 0 06 μg/ml for 4 h before virus, + = added, — = not added

‡ Assayed with vaccinia virus PDD_{50} = amount of interferon which depresses the plaque count to 50 per cent of controls[3]

To test whether actinomycin-treated cells produced some substance that interfered with or inactivated interferon, interferon was added to supernatants collected from actinomycin-treated infected cultures and the mixture titrated for interferon activity Sufficient interferon to inhibit 32 per cent of vaccinia virus plaques was added to the supernatant from infected, actinomycin-treated cultures which by itself would inhibit 21 per cent of vaccinia plaques The mixture was found to inhibit 39 per cent of vaccinia plaques which would be within the expected range of inhibition expected by a mixture of the two interferon preparations These results indicate that interferon-inhibiting material was not produced by infected and actinomycin-treated cultures

These findings suggest that the enhancement of virus growth by actinomycin was not a contributing factor in its ability to inhibit interferon production, and they provide further evidence for a direct effect of the antibiotic on some cellular mechanism involved in interferon production

Henderson and Taylor[4] have reported that Mayaro virus inactivated at 56° for 2 h was incapable of producing interferon Western equine encephalomyelitis virus, inactivated by prolonged incubation at 37°, was shown to be capable of interfering with active virus[5], but Lockart[6] afterwards showed that such inactive virus did not produce measurable amounts of interferon in *L* cells Vilček[7,8] found that tick-borne encephalitis virus inactivated by incubation at 56° or by prolonged incubation at 37° did not induce interferon production It is difficult to interpret the negative results since it is possible that the treatment may have rendered the virus incapable of entering the cells so that production of interferon could not be induced It is also possible that the stability of the viral nucleic acids to such treatment may differ with respect to interferon inducibility as well as to infectivity The results reported here are the first published evidence of interferon production by inactive arboviruses, although it has previously been shown that several arboviruses exposed to cells at relatively high temperatures at which little or no multiplication of virus occurred still produced large yields of interferon[9]

We thank Mr C Gilchrist and Mrs Barbara Knight for their assistance

MONITORING OF SEA-WATER FOR IMPORTANT RADIOISOTOPES RELEASED BY NUCLEAR REACTORS

By DR NOBORU YAMAGATA and KIYOSHI IWASHIMA
Institute of Public Health, Tokyo

IN view of possible increase in the discharge rates of radioisotopes into the sea, an analytical technique to measure very low concentrations of radioisotopes in sea-water has been developed

The conventional method of scavenging, namely, the precipitation of mixed ferric hydroxide and barium sulphate, failed to prove itself because of its very slow filtration The fact that marine manganese nodules are enriched with heavy metals and the rare earths[1] inspired us to examine commercial manganese dioxide, and it was found an effective and easily filterable scavenger for most of the radioisotopes which were reported to be present in reactor coolant water

A radioisotope, carrier-free or of high specific activity, was added to 50 ml of sea-water and then the mixture was shaken with 0 50 g reagent-grade powdered manganese dioxide for 10 min in a slightly alkaline condition (*p*H 8 2) Table 1 summarizes the results of experiments Important corrosion products except chromium, and fission products other than strontium and cæsium, were effectively picked up by 1 per cent (w/v) quantity of powdered manganese dioxide Further experiments to find the optimum quantity of scavenger showed 0 35 per cent to be the minimum for effective removal

Table 1 REMOVAL OF RADIOISOTOPES IN SEA-WATER BY SHAKING WITH POWDERED MANGANESE DIOXIDE

Radioisotope	Removed (%)
^{54}Mn	100 1 ± 0 2
$^{55\ 59}$Fe	96 1 2 3
^{60}Co	100 0 0 1
^{65}Zn	99 9 0 1
^{95}Zr-^{95}Nb	99 9 0 1
^{106}Ru-^{106}Rh	100 0 0 1
^{144}Ce	99 8 0 1
^{51}Cr	14 5 1 2
^{89}Sr	39 3 0 7
^{137}Cs	1 8 0 1

Partial permissible concentrations of cobalt-60 and iron-59 in sea-water recommended by the U S National Academy of Sciences—National Research Council are respectively 3×10^{-9} and 5×10^{-9} μc /ml for harbours[2] Since 100 l of sea-water had to be processed in order to detect referred concentrations of radioisotopes, granular manganese dioxide (20–60 mesh) was examined for its time-saving and scavenging efficiency in the filtration in a larger-scale operation Three litres of sea-water containing cobalt-60 were mechanically agitated after the addition of ten grams of granular scavenger After 105 min of agitation 98 2 per cent of the activity was removed from the liquid phase, and fixation on the scavenger still remained after standing overnight.

One hundred litres of sea-water were collected in Sagami Bay, off Enoshima, at 35°16′N , 139°28′E on July 9, 1963, to check the feasibility in full-scale operation of the proposed method To prevent loss by possible adsorption of trace activities to the container, collected waters in five polyethylene containers, 20 l each, were treated *in situ* with 70 g each of granular manganese dioxide and transported to the laboratory After 2-h agitation and settling overnight, the scavenger, 350 g altogether, was filtered off and transferred into a polyethylene assay cylinder of 3 in diameter This was placed on top of the crystal (3 in × 3 in) of sodium iodide, inside 1-in -mercury and 4-in -lead shields, and the γ-spectrum taken for 1,000 min by means of a 256-channel pulse height analyser

Recognizable photo-peaks above the background response of the detector were 0 72–0 77 MeV, corresponding to zirconium-95 and its daughter niobium-95, and 0 52 MeV, corresponding to rhodium-106, the daughter of ruthenium-106 Comparison made with spectra from adding known amounts of the radioisotopes to 350 g of scavenger showed the concentration of 1 5×10^{-9} μc zirconium-95 + niobium-95 and 4 9×10^{-9} μc ruthenium-106 per millilitre of sea-water, the latter being calculated by neglecting the presence of ^{103}Ru–^{103}Rh

Table 2 DETECTION LIMITS OF THE PROPOSED METHOD FOR CERTAIN RADIOISOTOPES WHICH MAY BE PRESENT IN SEA-WATER WHEN APPLIED TO 100-l -SAMPLE

Radioisotope	Photo-peak energy MeV	Detection limit in sea-water μc /ml	Partial permissible concentration in sea-water* μc /ml
^{60}Co	1 17	1×10^{-9}	
	1 33	2×10^{-9}	3×10^{-9}
^{59}Fe	1 10	2×10^{-9}	
	1 29	3×10^{-9}	5×10^{-9}
^{65}Zn	1 12	1×10^{-9}	2×10^{-8}
^{95}Zr	0 72	2×10^{-10}	3×10^{-8}
^{95}Nb	0 77		5×10^{-7}
^{106}Ru	0 52(^{106}Rh)	2×10^{-9}	1×10^{-8}

*For harbours, estuaries, and inshore waters within 12 miles of the coast-line Recommended by N A S -N R C [1]

Detection limits of the proposed method are summarized in Table 2 for several important radioisotopes The limits for cobalt-60 and iron-59 are from a half to one-third of the recommended partial permissible concentrations for harbours while those for the other radioisotopes are even less This would indicate the practical usefulness of the proposed method for monitoring when distinction between cobalt-60, iron-59 and zinc-65 cannot be made easily, that is, when radioisotopes exist together The detection limit for cerium-144 would lie above its permissible concentration of 1×10^{-9} μc /ml because of the high background counting rate in the spectral region of low gamma energy Cæsium-137 remains in the filtrate from the scavenger and can be determined by a molybdophosphate scavenging method followed by gamma spectrometry, a report of which is in preparation

Neither the mechanism of pickup by manganese dioxide nor the physical states of trace elements in sea-water are clearly known and investigations are in progress About 8×10^{-3} μc of cobalt-60 in a 2-l sample of water from the thermal shield of a nuclear reactor was completely removed by the proposed method, this suggests the possibility of using manganese dioxide in place of organic ion-exchange resin in purifying hotter reactor water in closed-cycle reactor systems

Sea-water samples were collected from three locations between the end of July and the beginning of August 1963 (1) the Sasebo Harbour, Kyushu District, an important port at which the United States nuclear-powered ships are expected to call, 33°08′N , 129°43′E , (2) the Inland Sea, off the Kure Harbour, an important fishing area, 34°06′N , 132°37′E , (3) Tsuruga Bay, near the expected power reactor site, 35°44′N , 136°03′E Zirconium–niobium-95 and ruthenium-106, both of which are considered to have originated from radioactive fall-out released by nuclear weapon tests, were found in the samples in the following concentrations, respectively, 1 3 and $5{\cdot}9 \times 10^{-9}$ (location 1), 1 0 and 4 7×10^{-9} (location 2) and 2 6 and 11 8×10^{-9} μc /ml (location 3) The level of ruthenium-106 in the sea-water from location 3 indicated more than the recommended permissible level of 1×10^{-8} μc /ml for harbours However, the result for ruthenium-106 could not be taken as more than a maximum estimate because it was calculated by neglecting the presence of ruthenium-103 The higher levels of the fission products in the sea-water from Tsuruga Bay may be contributed to the heavy snow-fall in winter and leaching by river of the accumulated radionuclides

OPTICAL ACTIVITY IN OILS DERIVED FROM COAL

By CHARLES ZAHN, STANLEY H. LANGER*, BERNARD D. BLAUSTEIN
and IRVING WENDER

Pittsburgh Coal Research Center, U.S. Bureau of Mines, Pittsburgh

COAL is a product of the progressive fossilization of plant materials. Since optically active substances are widespread in living matter, it is not surprising that optically active materials have been isolated from peat moss[1], peat[2], lignite[3] and from the montan wax of brown coal[4,5]. Both positive and negative rotations have been observed in > 180° C distillates of a saturated hydrocarbon oil from a benzene extract of a Saar bituminous coal[6]. Fractions of positive rotation have been found in neutral oils from tars of Saar and Rhine coals processed above 450° C (ref. 7).

During an examination of the composition of synthetic liquid fuels from coal at the U.S. Bureau of Mines, the question arose whether some of the optically active centres in coal would survive the rigours of high-temperature, high-pressure, catalytic hydrogenation. An exploratory study of a once-through re-cycle oil (used in the hydrogenation of Rock Springs, Wyoming, coal with ammonium molybdate catalyst at 450°–525° C and at 8,000 p.s.i.g.) disclosed that many distillates were indeed still optically active[6]. This finding prompted an examination into the nature and occurrences of optically active substances in other oils, including low-temperature carbonization tars (Table 1).

Table 1. COAL PRODUCTS EXAMINED FOR OPTICAL ACTIVITY

*Hydrogenation Products**	
Rock Springs, Wyoming, coal (*hvCb*)†	once-through re-cycle oil
West Kentucky and Pittsburgh coals	petrols‡
Velva, North Dakota lignite	middle oil (*A*)§
Pittsburgh seam coal (*hvAb*)†	middle oil (*B*).
Carbonization Products‖

Sandow, Texas, lignite	tar, Aluminium Co. of America (*D*).
Pittsburgh seam coal	tar, Consolidation Coal Co. (*E*)

* These oils were products of the Bureau of Mines' pilot-plant operations at 450°–525° C and about 8,000 p.s.i.g. pressure, and with mainly ferrous sulphate as catalyst, excepting the re-cycle oil, for which ammonium molybdate was the catalyst.

† Designations of coal rank: high-volatile *C* bituminous and high-volatile *A* bituminous.

‡ An equi-volume mixture of petrols obtained separately from the coals.

§ These italicized letters are used in the text to designate the products.

‖ From low-temperature carbonizations.

Optical activity was observed in almost all the distillates from the carbonization tars and in the majority of the distillates from the hydrogenation oils. No activity was observed in the tar-acid and tar-base fractions examined. Optical activity probably would diminish with increasing coalification, but oils from coals of carbon content above 84 per cent were not examined. Generally, the methods of isolating optically active concentrates included distillation, liquid chromatography on silica gel, and adduction with urea. Although the individual compounds responsible for the optical activity in the various concentrates have not yet been isolated, the experimental findings indicate that, as the separations progressed, the optical activity segregated mainly with the branched-chain–naphthenic and hydroaromatic fractions, and occasionally with cyclic olefines. We believe that the observed optical activity is due to cyclic structures.

The distillate fractions from oils *B* and *E* (Table 1) gave only positive rotations, but those from the other sources exhibited positive and negative rotations. The lowest boiling, optically active distillate observed had b.p. 119°–124° C, α_D −0·19° (tar *C*). Mass spectral analysis of this and of some successive distillates showed that alkyl*cyclo*hexenes reached a maximum concentration simultaneously with the observed maximum in optical rotation. The fraction with these maxima had b.p. 124°–131° C, α_D −0·33°. Tar *D* also yielded active olefinic material, b.p. 121°–133° C. Mass spectrometry of a chromatographic eluate (α_D^{24} − 0·51°), before and after hydrogenation, indicated the major compounds present were C_8-cyclic olefines; the fragmentation patterns of the hydrogenated sample indicated a mixture of C_5- and C_6-ring compounds.

Besides activity in hydrocarbon fractions, the neutral oil from tar *C* showed activity in a fraction strongly adsorbed by silica gel. Infra-red and ultra-violet spectrometry of the most active distillate of the ethanol-eluted material (α_D^{24} −0·22°, b.p. 187° C) indicated the presence of an appreciable concentration of a molecule containing a carbonyl group conjugated to an olefinic group.

Fig. 1 indicates the optical rotations for the successive distillates of oil *A*. Two combinations of neutral-oil vacuum distillates from oil *A* (b.p. 230°–260°, 260°–275° C/760 mm) after chromatography on silica gel and treatment of the heptane-eluted oil with urea and chromatography of the non-adducting oil afforded a combined heptane-eluted concentrate, α −0·43. Mass spectrometry of this concentrate showed it contained C_{12}–C_{16} compounds with peak-height maxima at $C_{14}H_{28}$ and $C_{14}H_{26}$ and that the mixture consisted of about 10 per cent branched-chain paraffins and about 90 per cent uncondensed C_5- and C_6-rings and 2- and 3-ring condensed naphthenes. Ultra-violet spectrometry of the concentrate indicated the absence of aromatic compounds.

The two most active concentrates came from distillates, b.p. 260°–275° C, of oil *A*. The first concentrate had $[\alpha]_D^{26}$ +1·8 (*c* 20, heptane), the second $[\alpha]_D^{26}$ +7·4 (*c* 14, heptane). These samples contained appreciable concentrations of hydroaromatic or polyalkyl-substituted aromatic material as shown by: (*a*) their liquid-chromatographic behaviour, (*b*) ultra-violet spectra containing band maxima at 268, 272, 278 mμ, (*c*) low-ionizing voltage mass spectrometry of the first concentrate, which, although showing a wide range of molecular weights, chiefly gave peak-height maxima at 204 and 218 (alkylbenzenes ?) and 202 and 216 (alkylindanes or alkyltetralins ?).

* Present address: American Cyanamid Co., Stamford, Connecticut.

Although our work has not ruled out the presence of optically active acyclic compounds in the oils, these compounds probably would have been racemized on heating with inorganic catalysts[9] or with carbon[10]

The general opinion is that both coal and petroleum resulted from biochemical and geochemical transformations of living matter Apparently, optically active naphthenic units persisted with petroleum[11] as well as with coal We observed optical rotation in coal-derived oil boiling as low as 120°, whereas it was reported[12] that activity begins only to appear in petroleum oil boiling at about 280° It must be realized, however, that this petroleum was an untreated natural product, whereas our coal-derived oils are mainly products of degradations that yielded lower-boiling active compounds

Retention of optical activity by the cyclic compounds in oils from thermal carbonization and catalytic hydrogenation of coals might be explained by degradation of the coal macromolecule into cyclic compounds possessing at least one optically active quaternary carbon atom, such compounds are probably highly resistant to racemization

Interestingly, optical activity has not been observed in lignin, in line with present-day theories of its formation and structure[13] Since the hydroxybenzene nucleus is a fundamental part of the lignin structure, the absence of optical activity in our phenolic fractions appears consistent with lignin being inactive Apparently the optically active material in coal arose from sources other than lignin, which has been proposed as a major progenitor of coal[14]

Other workers consider cellulose the primary source of coal[15] Conjecturably, cellulose may have been transformed by microbial action into products with optically active structural units that would persist in coal and survive catalytic hydrogenation. Various investigators[16] obtained coal-like products from the carbonization and catalytic hydrogenation of cellulose but none of these workers reported on observations for optical rotation However, the optically active materials in the oils from the coals probably derived mostly from the steroids[1] and the terpenes[2,3] in the coal precursors

We thank Dr R A Friedel for spectral analyses, and Mr Gus Pantages for assistance.

DATING OF POLARITY ZONES IN THE HAWAIIAN ISLANDS

By Dr. IAN McDOUGALL and D. H. TARLING

Department of Geophysics, Australian National University, Canberra

PERIODICITY of reversal of the Earth's magnetic field is of some geophysical and geological interest Study of the polarity of the Earth's field throughout geological time provides much information relating to the origin of the field, and the stratigraphical zonation of polarities in rock sequences may offer a valuable means of geological correlation

Brunhes[1] observed that the natural remanent magnetization of some rocks has a polarity opposed to the present sense of the Earth's field, and Mercanton[2] showed that rocks of different ages from different parts of the world are magnetized in this sense These observations led to the supposition that periodic reversals of the Earth's magnetic field may have occurred during geological time Hospers[3,4] found that in a sequence of Cainozoic lavas in Iceland polarity zones occur, and that some of these zones are separated by a thin zone of rocks with intermediate directions Since then, several levels of reversal have been recognized, and it appears that reversals are frequent in the Cainozoic in which rocks magnetized in the same sense as the present Earth's field (that is, 'normal') are about as common as rocks with a direction of magnetization opposite to that of the present field (that is, 'reversed')

Self-reversal[5,6] and reversals of the Earth's magnetic field appear to be the only mechanisms able to account for the common occurrence of rocks with exactly opposed polarities It is possible to test the hypothesis of reversal of the Earth's field by comparing palæomagnetic observations from various parts of the world, as one of the consequences is that rocks of the same age, irrespective of composition and geographical location, possess the same polarity It is therefore of interest to obtain accurate dates on the reversal sequences This article attempts to give a stratigraphic table of polarity zones in the Upper Cainozoic on palæomagnetic measurements and isotopic age determinations on samples of lavas from the Hawaiian Islands A summary of the magnetic observations was given earlier[7], and a description of the dating methods and results is given elsewhere[8,9] These results are consistent with palæomagnetic and age measurements made[10] on rocks from six sites in California, but they suggest the presence of two additional polarity changes and allow more precise dating of each level of polarity change This work goes some way toward establishing a stratigraphical sequence of polarity zones during the Upper Cainozoic against which other palæomagnetic results can be compared to test the hypothesis of reversal of the Earth's field

Sampling for palæomagnetic and age measurements was undertaken separately in the Hawaiian Islands, although in a number of cases the same sample, or samples from the same outcrop, were used for both measurements Hence, there is some uncertainty in the correlation between the measured ages and polarities observed in the same formation, but it is considered that the pattern that emerges is essentially correct, particularly as the age measurements show that many of the formations (as defined by Stearns and Macdonald and summarized by Stearns[11]) were erupted over periods of 200,000 years or less

The dates were determined on whole-rock samples by the potassium–argon method. Argon was measured by isotope dilution and potassium by flame photometry. Determinations were made in duplicate in most cases, and the plus and minus figures quoted after an age indicate the range. The ages generally are precise to better than ± 3 per cent at the 95 per cent confidence-level.

A total of 164 samples were collected for palæomagnetic study from 59 sites in five of the Hawaiian Islands. The samples appear to be magnetically stable as the directions of magnetization remain constant in alternating fields[12] up to 750 œrsteds (peak), and only directions observed in samples after treatment in a magnetic field of 150 œrsteds (peak)[13] are considered here. Stability is also indicated by a high average coercivity of maximum isothermal remanence (445 œrsteds) and the consistency of results both within and between different sites in the same formation. The direction observed is thought to reflect the actual direction of the past magnetic field as 16 specimens that were heated and then cooled in the present Earth's field at Canberra (0·59 œrsteds) acquired directions parallel to the applied field. The results are listed in Table 1 and illustrated in Fig. 1.

Table 1. PALÆOMAGNETIC AND AGE DATA ON ROCKS FROM THE HAWAIIAN ISLANDS

Formation	Polarity (*N*, 'normal', *R*, 'reversed')	No. of palæomagnetic sites	K–Ar age (m.y.)	No. of samples dated, or sample No.
Hana (East Maui)	*N*	3	< 0·4	—
Kula (East Maui)	*N*	6	0·86, 0·43	2
Honomanu (East Maui)	*R*	1	> 0·86	—
Honolua (West Maui)	*R*	1	1·15 ± 0·02	4
Wailuku (West Maui)	*R*	5	1·29 ± 0·03	3
Lanai	*R*	3	—	—
East Molokai	*R*	6	1·3 –1·5	5
West Molokai	*R*	4	1·85 ± 0·01	1
Koolau (East Oahu)	*R*	8	2·2 –2·5	5
Waianae (West Oahu)	*N*	1	2·76 ± 0·02	*GA* 556
	N	1	2·84 ± 0·02	*GA* 809
	R	8	2·95 ± 0·06	*GA* 557
	N	2	3·27 ± 0·04	*GA* 810
Koloa (Kauai)	*N* and *R*	2	—	—
Napali (Kauai)	*N*	3	4·5 –5·6	3

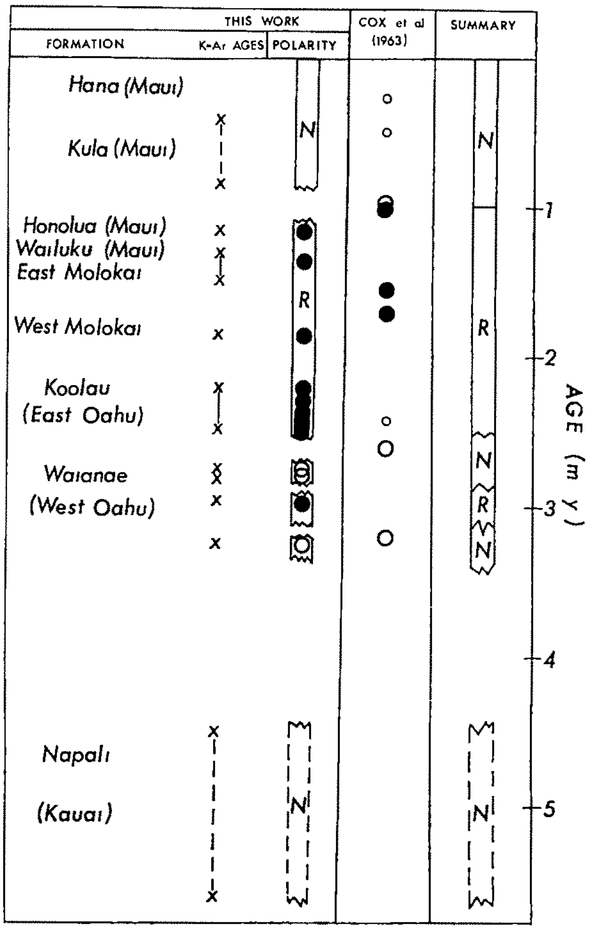

Fig. 1. Summary of palæomagnetic and age data. (Filled circles, 'reversed' polarity, open circles, 'normal' polarity.)

The polarity of the Kula and Hana Volcanic Series of East Maui is 'normal'. Potassium–argon age measurements on two samples from the Kula Series yield ages of 0·45 ± 0·02 and 0·84 ± 0·04 m.y. The older age was obtained on a sample from a lava immediately overlying the Honomanu Series, hence, this age probably closely dates the beginning of the eruption of the Kula Series. It is therefore likely that the specimens on which the magnetic measurements were made are not older than 0·84 m.y. The Hana Volcanic Series, which overlies the Kula Series, must be younger than 0·45 m.y. One site in the Honomanu Series is 'reversed', but the age of these lavas only is known to be older than 0·84 m.y.

Samples from a single site in the Honolua Series of West Maui are 'reversed'. A specimen from the same lava flow yields an age of 1·16 ± 0·02 m.y., and three other samples from the Honolua Series have measured ages agreeing at 1·15 ± 0·02 m.y. Hence, the results suggest that between 0·84 and 1·15 m.y. a change in polarity occurs.

The Wailuku Series of West Maui, underlying the Honolua Series, has 'reversed' polarity, and three samples from this formation yield ages agreeing at 1·29 ± 0·03 m.y. One of the six sites sampled for magnetic measurements has 'normal' polarity, but as the inclination is negative (–49) compared with the average of all other 'normal' sites (+35) from Hawaii this result is clearly anomalous and is not included.

The seven East Molokai sites show 'reversed' polarity, and age measurements of five samples indicate that the formation is 1·3 to 1·5 m.y. old. Two of the samples used for the age determinations are probably from the same lava flows as two of the sites sampled for magnetic measurements. The West Molokai lavas also have 'reversed' polarity, and the single specimen dated from this formation has an age of 1·85 ± 0·01 m.y.

Sites on the Island of Lanai are all 'reversed', but no age measurements were made on these rocks. As Lanai lies between Molokai and Maui it may be inferred that the age of these volcanics is probably about 1·3 m.y.; this is consistent with the 'reversed' polarity of the Lanai rocks.

Samples from five of the eight sites in the Koolau Series of East Oahu were also used for the age determinations. All the sites are 'reversed', and the ages range from 2·2 to 2·5 m.y. Two sites sampled in the Honolulu basalt are 'normal', but these were not dated, and only are known to be less than 2·2 m.y.

Two samples from the Upper Waianae Series of West Oahu yield ages of 2·76 ± 0·02 and 2·84 ± 0·02 m.y., and have 'normal' polarity. A lava of the Lower Waianae Series dated at 2·95 ± 0·06 m.y. has 'reversed' polarity, and a further sample from the same formation at a different locality has 'normal' polarity and is dated at 3·27 ± 0·04 m.y. Other sites in the Waianae Series also have 'reversed' polarity.

Three samples from the Napali Formation of Kauai[14] yield ages ranging from 4·5 to 5·6 m.y., and the polarity at three different sites is 'normal'. However, as the sites from which the samples for magnetic and age measurements were collected are widely separated, it is not possible to make precise correlations. Samples also were dated from the Makaweli Formation of Kauai, but no rocks were collected for palæomagnetic measurement. In the Koloa Series of Kauai both 'normal' and 'reversed' polarities were found. The single specimen dated from this formation is not from the same locality as any of the palæomagnetic sites, hence no correlation is possible

It may be assumed that the 'reversed' polarities observed in Hawaiian rocks are caused by reversal of the Earth's magnetic field This is supported by the observation that rocks of each polarity occur in discrete stratigraphic zones, and that in each of these zones the composition of the lavas ranges from picrite basalt to trachyte In addition, there is no evidence of self-reversal in specimens examined in the laboratory However, these observations do not refute the possibility of self-reversal, and it is necessary to compare the results from Hawaii with results from rocks of similar age in other parts of the world if the hypothesis of reversal of the Earth's field is to be substantiated

Our data are consistent with the change from 'normal' to 'reversed' polarity observed[10] in California (Fig 1) at about 1 m y, but suggest that a return to 'normal' polarity occurred between 2 5 and 2 75 m y, rather than at about 2 m y as inferred by Cox *et al* [10] They recorded 'normal' polarity in a rock dated at 2 6 ± 0 1 m y. and refer to Rutten[15], who reported 'normal' polarity in a sequence in Italy dated at about 2 4 m y These data, combined with our measurements, suggest that the change from 'reversed' back to 'normal' polarity occurred at 2·5 ± 0 1 m y The 'reversed' polarity found in a rock from the Waianae Series with a measured age of 2 95 m y indicates that the behaviour of the magnetic field is more complex than has been suggested previously. Owing to the lack of data it is not possible to state whether 'normal' polarities found in rocks dated at 3 3 and about 4 5 m y belong to the same magnetic epoch or whether a zone of 'reversed' polarity occurs during this period Our results are consistent with varying frequency of change in the polarity of the Earth's magnetic field in the Upper Cainozoic, rather than a regular change about every 1 m y [10].

Roche[16,17] showed that in France lavas of Upper Pleistocene age are normally magnetized, and that lavas of Villafranchian (Lower Pleistocene) age have 'reversed' polarity Hence, the change in polarity at about 1 m y found in the Hawaiian Islands and in California may be correlated with that found in France The stratigraphic position of the return to 'normal' polarity has not been established in France, but it is either in the lower part of the Villafranchian or in the Astian[18], although Rutten[19] suggested that it occurs at the base of the Villafranchian Clearly it is of importance to establish the position of this boundary in order that correlations may be made with greater certainty throughout the world Fourteen polarity zones were reported by Khranov[20] from sequences of Upper Cainozoic age in Russia, but at this stage it would be premature to attempt direct correlations

The evidence from Hawaii supports, but does not prove, the hypothesis of changes in polarity of the Earth's magnetic field Further study on rocks of similar age clearly is necessary to confirm the hypothesis, and to place closer limits as to the times when polarity changes occurred The present work suggests that models of the Earth's magnetic field should account for irregular periodicity of reversal

We thank E Irving for his advice

ABSORPTION IN RADIO SOURCES OF HIGH BRIGHTNESS TEMPERATURE

By P. J. S. WILLIAMS

Mullard Radio Astronomy Observatory, Cavendish Laboratory, University of Cambridge

THE discrete radio sources have continuous spectra which generally follow a power law, $S \propto \nu^{-\alpha}$ (S = flux density, ν = frequency), and the usual graph of log S against log ν is a straight line It is generally believed that most sources are galaxies and that the radiation is synchrotron radiation from relativistic electrons, the straight radio spectrum then implies a population of relativistic electrons with an energy distribution which also follows a power law $N(E) \propto E^{-(2\alpha+1)}$ However, there are sources the spectra of which deviate significantly from a straight line, and it has been noticed[1] that these sources tend to have high surface brightness

Recently, improved measurements at 38 Mc/s have shown that, in a few sources, the flux density actually falls at low frequencies (Fig 1), and these sources also have the smallest known angular diameters and the highest known surface brightness In the case of 3*C* 147, the decrease in flux density between 81 5 Mc/s and 38 Mc/s is so rapid that no cut-off in the electron energy spectrum, however sharp, would account for it These circumstances suggest that we may be observing synchrotron self-absorption

In Fig 1, the high-frequency data are taken from Conway, Kellermann and Long's paper[1] on the spectra of 160 sources The 38-Mc/s points are taken from a survey by J E Baldwin, S Kenderdine, and me, using the instrument described in ref 2 Flux densities at 81 5 Mc/s (3*C* 48, 147, 295, 298) and 85 Mc/s (3*C* 298) have been taken from refs 3 and 4 respectively, correction factors (0 85 and 0 75 respectively) have been applied to the

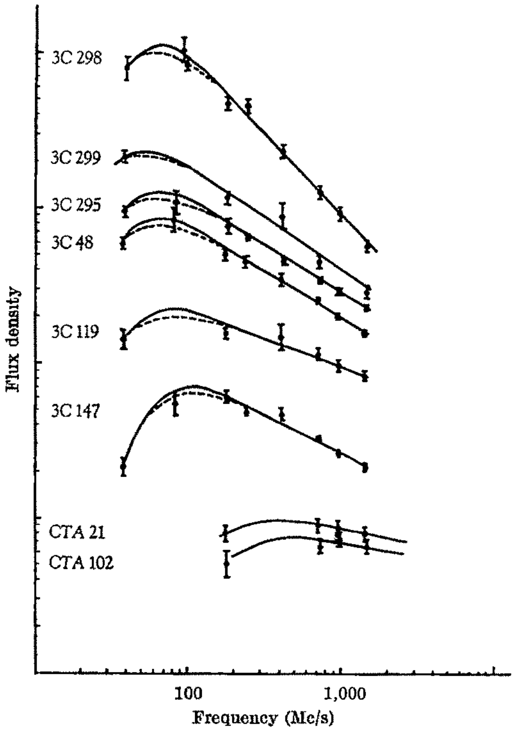

Fig 1 —, synchrotron absorption, - - -, thermal absorption

catalogue values of flux density, the factor being determined by a comparison of the flux densities of the strongest 'Class *S*' sources[1] with the values interpolated from the spectra given[1]

Two mechanisms of absorption could be held responsible for the cut-off in the spectra at low frequencies

(*a*) *Thermal Absorption.* This occurs if a layer of *H* II of appropriate optical depth, τ, lies between the source and the observer The spectrum would be

$$S = k\,\nu^{-a} \exp(-\tau) = k\,\nu^{-a} \exp(-A/\nu^2)$$

If a spectrum of this shape is scaled in both frequency and flux density to fit the observed values, we can calculate the emission measure of the *H* II layer necessary to cause the absorption The values quoted in Table 1 are $\int N_e^2\, ds$, where N_e = No of electrons/c c , and ds is distance through the layer, measured in parsecs

(*b*) *Synchrotron Self-Absorption* This occurs if the brightness temperature of emission is of the same order as the mean kinetic temperature of the relevant relativistic electrons, and so we should expect to observe this in sources of high enough brightness temperature

A detailed calculation by Le Roux[5] has shown that for a source in a uniform cube of side l, in a magnetic field of strength B,

$$S = l^2 \frac{\bar{\varepsilon}}{\chi} (1 - \exp(-\chi l))$$

where χl, the optical thickness,

$$= \frac{\mu a e^2 c l}{16\pi m_0} (\gamma + 2) \left(\frac{eB}{2\pi m_0}\right)^{(\gamma+2)/2} F'(\gamma) \nu^{-(\gamma+4)/2}$$

and $\bar{\varepsilon}$, the mean emission per unit volume,

$$= \frac{\mu a e^2 c}{8\pi r^2} \left(\frac{eB}{2\pi m_0}\right)^{(\gamma+1)/2} F''(\gamma)\, \nu^{(1-\gamma)/2}$$

If $N(E)\, dE$ = No of particles/unit vol with energies between E and $E + dE$,

$$= \text{const } E^{-\gamma}\, dE,$$

$$a = (\gamma - 1) \int_{m_0c^2}^{\infty} N(E)\, dE,$$

r = distance of the source from observer

$F'(\gamma)$ and $F''(\gamma)$ are numerical factors weakly dependent on γ If γ is determined by the spectral index at high frequency, the predicted spectrum can be scaled in flux density and frequency to fit the observed values and so indicate ν_m, the frequency at which the flux density is greatest

If synchrotron self-absorption is taking place, the predicted angular diameter of the source is then given by

$$\theta_p^2 = \frac{S_{400}}{(400\ 10^6)^{(1-\gamma)/2}} \left(\frac{eB}{2\pi m_0^3}\right)^{1/2} \frac{(\gamma + 2)\,(1 + z)^{1/2}}{\nu_m^{(\gamma + 4)/2}}$$

The 'observed' angular diameter, θ_0, is largely based on a single interferometer measurement at a spacing of 61,100 λ (ref 6), assuming that the source is single with a simple Gaussian brightness distribution However, very few sources have such a simple brightness distribution, many being made up of two separate components In such a case, θ_p corresponds to the sizes of individual components, while θ_0 corresponds to the dimensions of the source as a whole, and can only be used as a generous upper limit For example, a single interferometer measurement for *3C* 295 would only give $\theta < 12''$, more detailed measurements[7] have indicated that it is made up of two components 4″ of arc apart Each component is less than 1″ of arc wide on the line joining them, but 1 7″ of arc in length perpendicular to this line These dimensions give much better agreement with θ_p

The one clear and outstanding fact is that the six sources selected from the available data on the basis of their unexpectedly low flux-densities at 38 Mc/s all belong to the very small fraction of sources with angular sizes < 5″ of arc and exceptionally high surface brightness The high surface brightness suggests that synchrotron self-absorption may occur, but it is also possible that a source of such small size may lie entirely within the associated galaxy so that thermal absorption may take place

For both mechanisms, the observations can be fitted by calculated spectra representing reasonable physical conditions It is unlikely that improved spectral measurements will be able to distinguish between the two proposed mechanisms as the predicted spectra are based on very simple models, and will not apply in detail to a real source

In the case of *3C* 295, however, the two components are separated by more than 16 kparsecs, and it is probable that the radio emission occurs too far outside the galaxy to be absorbed appreciably by ionized hydrogen In this case, at least, synchrotron self-absorption seems the more probable mechanism

The two sources *CTA* 21 and *CTA* 102 are also included because they, too, have spectra with a maximum, but at much higher frequencies If these maxima are to be explained by synchrotron self-absorption, the sources must have linear dimensions of less than 150 parsecs (again assuming $B = 10^{-4}$ gauss, but making no assumptions about their distances)

While the known upper limits on angular diameters are consistent with synchrotron self-absorption, it is clearly desirable that more detailed measurements of brightness distribution should be made, if possible, so that a quantitative comparison can be made

I thank H van der Laan and P A G Scheuer for useful discussion of the synchrotron absorption mechanism

Ionization Coefficients in Helium at High Pressures

In recent years there has been considerable effort devoted to the study of the ionization processes which give rise to ionization growth in different gases. Of particular interest from the fundamental point of view is the growth of ionization in helium, because in this case quantum mechanical methods may be more easily applied than in the more complex case of diatomic gases. Consequently, direct comparison may be made between experimental data on ionization coefficients, for example, and the quantum mechanical computations. Despite its simple atomic structure, however, the existence of high-energy metastable states of the helium atom, as well as of the helium molecule, results in the possibility of highly complex ionization processes occurring in this gas[1-3]. Moreover, experimentally, helium is a difficult gas on which to make observations because it has the highest ionization potential (24.6 eV) of any known gas. Most common impurities have ionization potentials (<16 eV) appreciably lower than the ionization potential of helium, and are thus preferentially ionized by direct electron impact even when present in only small quantities. Furthermore, ionization of the impurity atoms and molecules can be produced by collisions of the second kind with helium atoms in the high-energy metastable states, and by high-energy photons produced in the gas by the transition of excited helium states (which all have energies >20 eV) to the ground-state. The effects of impurities, even when present in quantities as low as 1 part in 10^6, become increasingly important as the parameter E/p (E, the electric field, p, the gas pressure) decreases, because, as E/p decreases, the mean electron energy decreases and the ratio of ionized impurity atoms to ionized helium atoms then increases. These considerable experimental difficulties probably explain why there are so far no published data on the measurement of ionization growth in helium at high gas pressures and low values of E/p.

It is the purpose of this note to report preliminary measurements on pre-breakdown ionization currents in uniform fields in helium over the range $3 < E/p < 5$ V cm^{-1} mm Hg^{-1} for pressures between 150 and 560 mm mercury. The measurements were carried out using a specially designed parallel plate ionization chamber with electrode separation variable from 0 to 1.5 cm which will be described elsewhere. The apparatus was initially evacuated to a pressure of 8×10^{-8} mm mercury with a rate of rise of pressure about 4×10^{-8} mm mercury min^{-1} into a volume of 13 l. The only high-pressure samples of helium available to us at the beginning of the work were those supplied in high-pressure cylinders by the British Oxygen Co. (analysis of the gas: 99.5 per cent helium, 0.5 per cent neon, 10–20 v.p.m. oxygen and 10 v.p.m. nitrogen). This gas was purified by circulation at high pressure over an activated charcoal trap at liquid air temperatures, heated copper oxide and liquid air traps, and stored in a glass reservoir. The gas was admitted to the ionization chamber through two further traps at liquid air temperature and a high-impedance copper trap previously outgassed and which was designed to eliminate any trace of grease present in the gas from the circulating system. The ionization chamber itself was completely isolated from grease and vapours by the use of all metal taps and a bellows monometer for the measurement of gas pressure.

Initially, the samples of helium prepared in this way gave values of ionization coefficients which were not reproducible from sample to sample, but during the course of experiments over some months, which involved repeatedly filling the system with purified helium and subsequent evacuation (some 100 times in all), reproducible samples were obtained. The values of the first Townsend ionization coefficient obtained when the gas was in this state were the lowest for the whole series of measurements, being a factor of about 50 less than the initial values found. This result showed that the gas sample was reproducible and is consistent with the view that the samples were the purest that had been obtained by this procedure.

A typical log I, d curve when the gas was in this state is shown in Fig. 1. The curve was analysed using the procedure developed in this Department[4] and the values

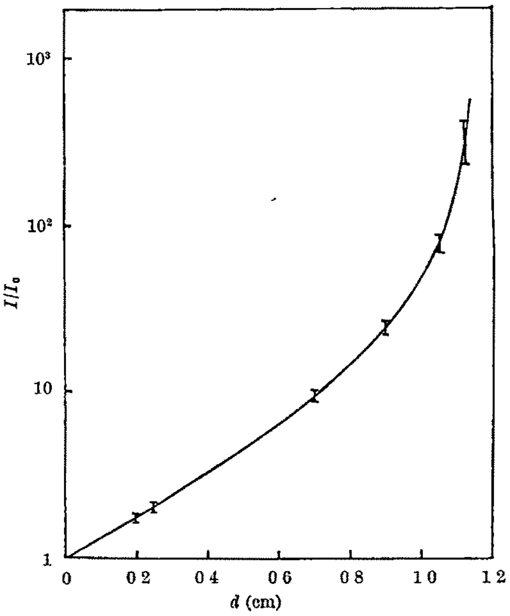

Fig. 1. Graph of log (I/I_0), d for helium at a pressure of 451.8 mm mercury and $E/p_0 = 4.00$ V (cm mm mercury)$^{-1}$. Full line gives the Townsend curve calculated for $\alpha = 2.83$ cm^{-1} and $\omega/\alpha = 0.04$.

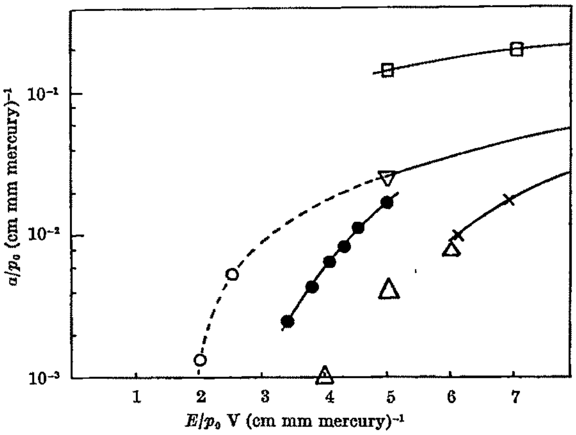

Fig. 2. Comparison of present experimental values of α/p_0 over high-pressure range 150–560 mm mercury with previous work at low values of E/p.

Experiment: Present investigation, —●—, ref. 7, —□—, ref. 8, —▽—, ref. 9, —×—. *Theory*: ref. 6, △, ref. 5, ○.

of the primary and secondary ionization coefficients obtained are shown on the figure. It is interesting to note that the experimentally observed growth is in agreement (well within the experimental error) with the generalized Townsend equation of growth with constant values of the coefficients α and ω/α.

The values of the primary ionization coefficient obtained from the measurements over the range of very low values of E/p from 3 to 5 V cm^{-1} mm Hg^{-1} are shown in Fig. 2. It was found that over a range of gas pressures of 150–560 mm mercury the similarity relationship $\alpha/p = f(E/p)$ was obeyed. Comparison of the present results with previous theoretically computed values[5,6] and experimental values[7–9] of α/p at higher values of E/p and lower pressures is made in Fig. 2, and it can be seen that the present results lie between the extrapolation of the experimental curves of Townsend and McCallum and those of Davies, Llewellyn-Jones and Morgan. Further work is in progress in attempts to obtain samples of gas at high pressures of higher purity and on the effects of known small amounts of impurities on the values of the ionization coefficients in helium.

Effect of Capacitor Arrangement on the Symmetry of Linear Pinch Discharges

All applications of linear pinch devices require that the current distribution in the discharge be symmetric about the axis of symmetry of the electrodes. Symmetry is not difficult to achieve when the energy supplied to the discharge is much greater than the minimum energy required for the discharge. However, certain applications, such as plasma accelerators for space-vehicles, require that the energy supplied be near the minimum value. When operating near the minimum energy condition, factors which may be unimportant for high-energy operation can have a marked influence on the discharge symmetry.

The effect of capacitor arrangement on the symmetry of a linear pinch discharge during the phase of the discharge when the current distribution was moving toward the axis was investigated using a pinch plasma accelerator[1]. Nine 10-μF capacitors, rated at 3 kV, were connected to 8-in. diameter aluminium electrodes by means of a 16-in. diameter parallel-plate radial transmission line. The discharge was initiated by briefly opening a solenoid valve which admitted a pulse of nitrogen into the previously evacuated interelectrode space. Four magnetic probes were inserted into the interelectrode space at the same radius at 90° intervals about the axis of symmetry of the electrodes. Probe signals were recorded simultaneously with the set of four probes positioned at various radii. The symmetry of the discharge was determined by comparing the magnitude and time of arrival of the signals.

When the nine capacitors were connected to the transmission line plates symmetrically, the discharge was found to be symmetric at capacitor voltages greater than 2.75 kV. The capacitors were then arranged asymmetrically by connecting them to the transmission line plates within a 270° angle, the other quadrant being vacant. For this case, symmetric discharges could not be obtained at 3 kV. This result indicates that when the capacitors are not arranged symmetrically, the current may not be distributed uniformly enough throughout the transmission line plates for a symmetric discharge to occur. This non-uniform current distribution is undoubtedly due to the tendency of the current to take the lowest impedance path to the electrodes. A similar effect probably also occurs with discharges in other geometries such as the coaxial plasma gun.

Electron Spin Resonance Evidence of Radiation-induced Electrons trapped in Organic Glasses at 77° K

It has been suggested in the radiation chemistry of the simple aliphatic alcohols, ethanol[1] and methanol[2,3], that γ-irradiation in the liquid state leads to the formation of positive and negative charged species:

$$2CH_3CH_2OH \rightarrow (CH_3CH_2OH)^+ + (CH_3CH_2OH)^-$$

The negative species, the solvated electrons, were shown to be involved in the chemical changes observed from their reactions with certain specific solutes: H$^+$, chloroacetate, 2-chloroethanol, diphenyl, naphthalene. More recently, various organic glasses[4] were irradiated at 77° K and in the case of ethanol[4,5] the absorption band formed at 5400 Å was accounted as due to solvated electrons. We present electron spin resonance evidence of radiation-induced electrons trapped or solvated in glasses at 77° K in the radiolysis of alcohols.

A conventional electron spin resonance spectrometer (Strand Laboratories, Inc., Model 601 *AX*) was used with a cylindrical reflexion cavity operating in the *T E* 011 mode, resonant frequency of the cavity 9,500 Mc/sec. All the alcohols were irradiated in thin 'Spectrosil' silica tubes in the absence of oxygen. Various alcohols have already been studied[6,7] by electron spin resonance, and some of the effects to be described here (ultra-violet irradiation and visible bleaching of unbuffered alcohols) were observed by these authors[6,7] without assigning an interpretation to them.

On γ-irradiation of, say, ethanol as a glass at 77° K it is known to turn to a dark purple colour and give a five-line paramagnetic resonance line. The intensity ratios of the lines are not binomial (1 : 4 : 6 : 4 : 1) at 77° K, the centre line appearing definitely more intense. The dark purple colour centres can be bleached by various means: (1) by thermal bleaching, when the temperature of the glass is increased to about 115° K, (2) by exposure at 77° K of the γ-irradiated glass to light in the visible range: the colour centres are rapidly bleached (2 min) by a white table-lamp light. Furthermore, on adding initially certain solutes such as acids, I$_2$, diphenyl, naphthalene, and 2-chloroethanol the purple colour is not formed on irradiation. All these solutes are known to react efficiently with electrons. The interesting observation is that following the foregoing methods when the irradiated glasses are colourless the centre line is attenuated while the five-line spectrum persists (in some cases becomes even stronger). It is therefore clear that the purple colour is associated with the single paramagnetic resonance line, which is nearly centred on the basic five-line spectrum of the $CH_3\dot{C}HOH$ radical. It was suggested[6] that this single line may be due to the positive ion of ethanol. However, the results obtained, particularly in the presence of various additives, are inconsistent with this suggestion. We

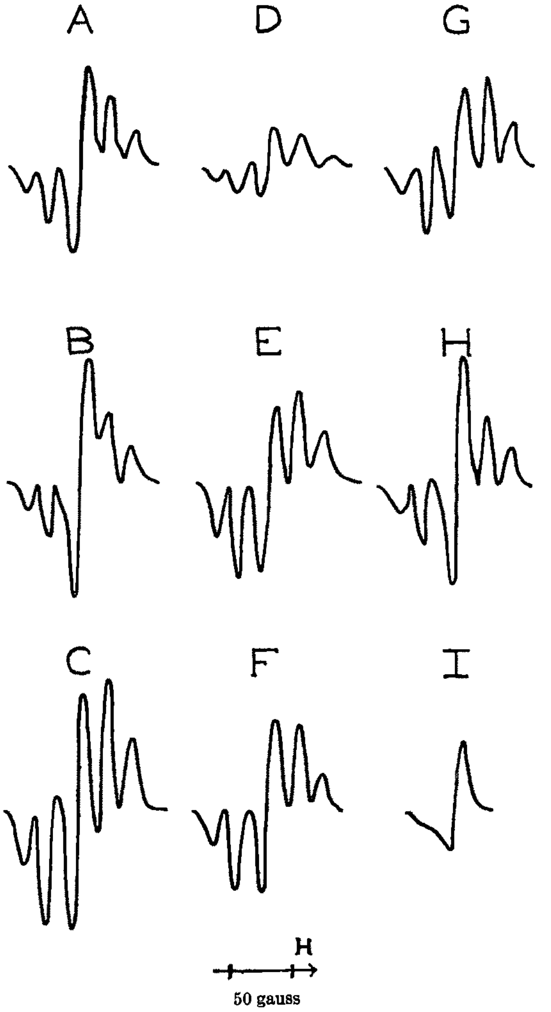

Fig 1 Electron spin resonance spectrum of γ-irradiated ethanol glasses at 77° K Total dose, 0 3 Mrad The spectra given were always observed at 77° K, and the same scale used (*A*) unbuffered ethanol, (*B*) 1 0 N sodium hydroxide in ethanol, (*C*) 1 0 N sulphuric acid in ethanol, (*D*) unbuffered ethanol warmed to 115° K, (*E*) 1 0 N sodium hydroxide after exposure to visible light, resulting in a bleached glass, (*F*) 0 1 M iodine in ethanol, (*G*) unbuffered ethanol after bleaching on exposure to visible light, (*H*) exposure of (*G*) to 2537 Å ultra-violet light, (*I*) warming (*G*) to 115° K until the five-line spectrum disappears

ascribe this line which is superimposed on the other lines to the electron trapped in the matrix at 77° K

The spectra in Fig 1 show some of the results referred to here On warming the neutral glass (*A*) to 115° K the centre line is reduced (*D*) and so is the total number of spins Presence of 1 N sulphuric acid (*C*) inhibits the formation of colour centres, reduces the centre line, and increases the intensity of the $CH_3\dot{C}HOH$ quintet as compared with (*A*) On addition of 1 N sodium hydroxide (*B*) the centre line increases, and the purple colour becomes even stronger Exposure to visible light results in rapid bleaching of the neutral (*G*) and alkaline (*E*) glasses, and a reduction of the centre line There is no change in the colour and electron spin resonance spectrum of the 1 N sulphuric acid glass (*C*) to visible light Subsequent to exposure to visible light, γ-irradiated neutral, acid, and alkaline ethanol, when exposed to ultra-violet light (2537 Å mercury lamp), result (*H*) in a decrease in the intensity of the basic five-line spectrum and an increase of another centre line superimposed on the 5-lines This new single line is relatively stable, and on warming to 115° K the $CH_3\dot{C}HOH$ radical disappears after a short period of time leaving the single line (*I*) which is seen to be disymmetric, and which seems to be due to the $CH_3CH_2\dot{O}$ radical It is to be noted that (*I*) is stable to visible light Full details and the suggested mechanism of formation of this radical will be given elsewhere

The presence of 0 1 M iodine (*F*) suppresses the colour of ethanol glass, attenuates the centre line, and reduces through secondary reactions the number of $CH_3\dot{C}HOH$ radicals stabilized at 77° K Presence of 1 0 M 2-chloroethanol also suppresses the colour and reduces the centre line In the presence of 0 1 M diphenyl the purple colour is not formed on irradiation, instead a blue-green colour is observed which is thought to be due to the mono-negative diphenyl radical ion[8]. The diphenyl ion gives under these conditions at 77° K a single centre line which is distinctly different from the centre line due to the electron Furthermore, the line of the diphenyl radical ion is relatively more stable to visible light

In conclusion, the electron spin resonance centre line obtained on irradiation of ethanol at 77° K is interpreted as evidence of radiation-induced electrons which are ejected from the solvent and trapped in these glasses The *G*-values (± 30 per cent) of the total paramagnetic species, that is, $G\ CH_3\dot{C}HOH + G(e)^-$, is 8 in unbuffered and 1 in N sodium hydroxide, and 10 in N sulphuric acid ethanol glasses Ge^- is 2, 3, and nil in the unbuffered, alkaline, and acidic ethanol, respectively

Electron spin resonance evidence of electrons was also obtained on irradiation of methanol and isopropanol Full details on all these alcohols, the various solutes used, and the photolysis of hydrogen peroxide in alcohol glasses will be published elsewhere

Surface Preparation of Electrodes for Studies of the Electrical Properties of Dielectrics

One of the major difficulties in the measurement of conduction currents and of the breakdown strength of homogeneous dielectrics is that of obtaining reproducible results This communication shows that to obtain such results mechanical polishing of the electrodes is to be preferred to the use of electrolytic polishing It has already been shown[1] that in liquid dielectrics the scatter in breakdown values is smaller for mechanically polished than for electrolytically polished electrodes

In the presence of an externally applied electric field, the overall behaviour of a dielectric medium is greatly affected by conditions at the electrode/dielectric interfaces, for example, oxide layers, adsorbed gases and vapours and surface roughness The idea that asperities on the electrode surfaces can cause field emission into a dielectric at applied fields well below the theoretically required value is well known[2,3]

In the case of liquid insulants it is extremely difficult to determine the conditions at the interfaces[4], but it is generally accepted that space charges will build up at the electrode surfaces due to the inevitable presence there of an effectively insulating layer The densities of the space charge concentrations will depend on the availability of ions in the bulk liquid and on the ability of the surfaces to neutralize them The intensification of the field at the cathode is further increased if there are protrusions or other irregularities on the surface[5,6]

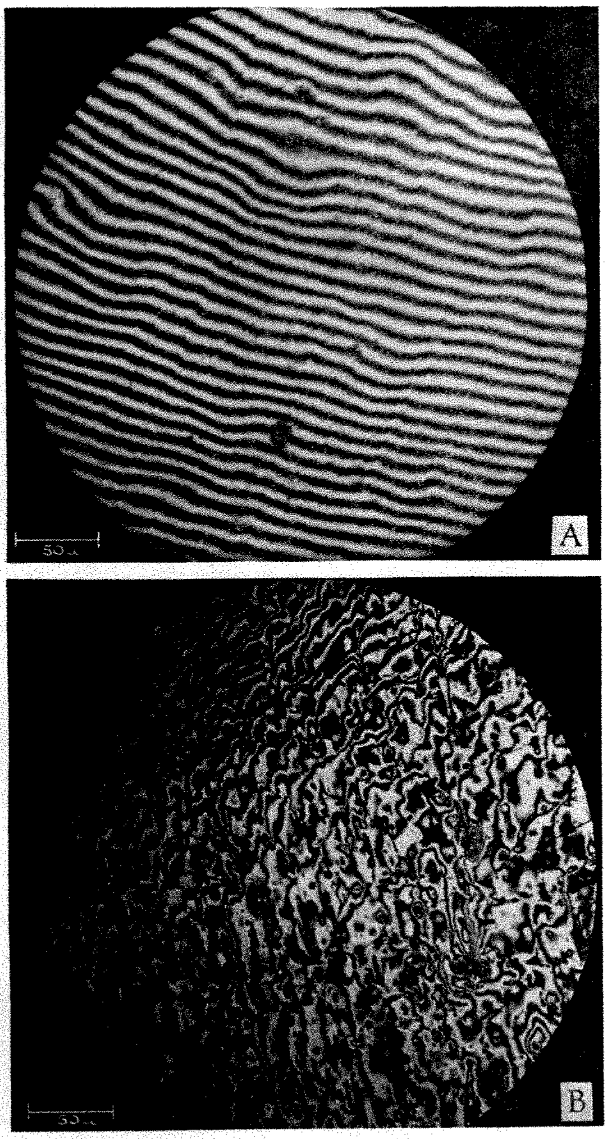

Fig. 1. Interferograms of polished magnesium surfaces. *A*, mechanically polished to 0·25μ diamond paste finish; *B*, electrolytically polished in a solution of three parts orthophosphoric acid and five parts ethyl alcohol

A first step, therefore, towards achieving reproducible results in measurements on liquid dielectrics is to obtain consistent electrode surfaces. Under normal experimental conditions it is not possible to control the oxidation of a surface but a method of producing a constant surface smoothness may be used.

Recent investigations[7], using electrode separations of up to 2 mm, have shown that electron emission from asperities can cause electrical breakdown in high vacuum. In longer gaps the removal by electrostatic forces of aggregates of material or impurities from the electrode surfaces ('clumps') is believed to initiate breakdown[8]. Therefore, to obtain possible improvements in the voltage holding of a given vacuum gap it is important to know what type of electrode preparation gives the smoothest finish.

For the foregoing reasons, an investigation was made of the two main methods of polishing electrode surfaces to determine the most suitable way of producing a consistently smooth surface. Fig. 1*A* is a typical interferogram of a mechanically polished magnesium surface and Fig. 1*B* is an interferogram of an electrolytically polished surface. The pattern produced by the electrolytically polished surface is very complex, showing that the surface is rough. Mechanical polishing produces a distinct and simple pattern which can be readily interpreted. In the example shown in Fig. 1*A* the maximum depth of a depression is $1{\cdot}4 \times 10^{-4}$ mm, the maximum height of a high spot is 2×10^{-4} mm and the scratches are 2×10^{-5} mm wide. Mechanical polishing also gives a reproducible surface finish which cannot be obtained by electrolytic polishing. In addition to producing a surface which may be even less permeable to electrons than natural oxide films[9], electrolytic polishing may give rise to a highly irregular surface with pits where impurity inclusions are preferentially dissolved and protrusions where these are less soluble than the bulk metal. The microgeometry of an electrolytically polished surface is therefore much more sensitive to the inhomogeneities of the metal than is a mechanically polished one.

We thank the Director of C. A. Parsons and Co., Ltd., for permission to publish this communication, Dr. R. L. Craik for help in preparing the surfaces and Mr. G. H. Hickling for helpful discussions.

Phantasies on a Natural Unity of Mass

THE 'artificial' unity of mass has not been solved for more than half a century and its substitution by a 'natural unity' cannot be considered as forthcoming.

However, it would seem that the day is not far off when a material can be identified, probably in crystalline form, which will be apt to define mass unity better than the actual microcrystalline league.

In so far as the choice of the physical status of the standard material is concerned, it should be noted that the use of a gas (for example, hydrogen) instead of a solid would present two insuperable drawbacks.

The first is that, if the pressure were not too high, the container would have to have considerable dimensions and a mass comparable with that of the gas contained inside.

The second drawback is that counting the atoms (for example, previously ionized), if made one after the other, with the quickest technical means (for example, with a counter capable of 10^7 atoms per sec) would require a longer time than the estimated age of the universe. The atoms to be counted are indeed in this case 3×10^{26} for each kg, while the number of seconds in two thousand millions of years is about 6×10^{16}.

A liquid would show other drawbacks.

A crystal, scaled so to result outside in a form of cube with faces parallel to the reticular planes—the number K of total elements being the same—in comparison with a gas offers the advantage to limit the number of elements to be counted down to three times the cubic root $(=3\sqrt{K})$. Therefore it gives the possibility of making the count in a reasonable time.

In this case the element or elements constituting the material should be mononuclide, with impurities not exceeding about 10^{10} and with an amount of dislocations or other defects also not greater than this percentage. Germanium, which seems to be satisfactory so far as impurities and dislocations are concerned, is not naturally a mononuclide; hence it could be used with difficulty, at least until simpler methods can be found for the separation of isotopes. Therefore, other elements or composite materials should be taken into consideration for the time being.

So far as the new definition is concerned, monocrystals should be first prepared with mass very near to 1 kg^2 and it should be compared with the standard of Sèvres, by means of the conventional balances and trying to reduce the comparison errors within one part in 10^9. (In the Italian National Metrology Commission, to avoid the known confusion between mass kilogram (kg) and kilogram-weight (kgp), a new name 'bes' has been suggested instead of 'kgp' by Prof. Polvani, now president of the Consiglio Nazionale delle Ricerche.

Secondly, using at first methods also partially destructive, as perhaps the electron microscope, or better, the field emission microscope, the number of atoms aligned on each of the crystallographic axis should be counted. Alternatively, the distance between two reticular planes should be measured with an error not exceeding one part in 10^{10}, and also the outer dimensions of the crystal (supposed cubic, for example) should be measured with the same accuracy.

From this moment onwards we can say: "The kg is the mass of K atoms of . . . ". The numerical count of the atoms will also give a highly accurate value for the Avogadro's number N, the knowledge of which—so far as is known—is now limited to one pair of parts in 10^5.

Afterwards, the uncertainty in determination of the K value can be artificially eliminated: the round figure obtained in this way could be assumed as the new unit of mass.

The procedure outlined here is practically similar to that followed for the unity of length, when the 'optical meter' has replaced the metallic m meter of Sèvres.

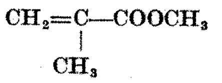
GEOLOGY

Use of Polymethyl Methacrylate in preparing Thin Sections of Recent Sediments

In the examination of Recent sediments it is necessary to identify accurately the mineral grains and lithic fragments which make up the deposit. Compositional properties such as the quantity and type of quartz, feldspar, calcite and the lithic, or rock, suite are keys to the proper interpretation of source and dispersal of a sediment. Such properties as diagenetic alteration of grains, mineral inclusions and specific rock types can be determined only by optical study of specially prepared petrographic thin-sections.

Polymethyl methacrylate, an acrylic compound with the structural formula:



$$CH_2{=}\underset{\displaystyle CH_3}{\underset{|}{C}}{-}COOCH_3$$

was selected as the matrix mounting medium because molecular cross-linkages act as three-dimensional tie bars, thus giving great strength to the matrix. The polymerization can, also, be carried out quickly and without heat at room temperature. Furthermore, when polymethyl methacrylate is used and mixed properly, there is only 4 per cent, or less, volume contraction of the medium, and there is no effect from external heat or caustic chemicals on the polymerized product.

Polymethyl methacrylate is obtainable from Claudius Ash, Sons and Co., Ltd., 26–40 Broadwick St., London, W.1, where it is marketed under the trade name 'Stellon', a denture repair material.

The step-by-step procedure for making a petrographic slide of Recent sediment using polymethyl methacrylate (hereafter termed 'Stellon') is as follows:

(1) Assemble the following tools and supplies: (*a*) microscope slides, frosted, 1½ in. × 3 in.; (*b*) wire, flat, approx. ⅛ in. by 1/16 in., for use in shaping a rectangular mould to hold the medium; (*c*) crucible, about 1½ in. diam., ¼ in. deep, for mixing the acrylic; (*d*) spatula, stainless steel, with a blade about 1 in. long and ¼ in. wide; (*e*) 'Plasticine', ¼ lb., to be used in positioning the wire mould and to prevent leakage of the slurry; (*f*) petroleum jelly ('Vaseline'); (*g*) one 'Stellon' kit, consisting of 4 oz. of powder and 4 oz. of fluid; the clear type, non-pigmented powder must be used.

(2) Using the specified flat wire, make a rectangular mould about 1⅛ in. by ¾ in. in size. The mould is positioned on the frosted glass slide using banked-up 'Plasticine' to prevent leakage and air bubbles from forming prior to hardening. A thin smear of petroleum jelly over the glass will prevent subsequent sticking.

(3) Mix, in crucible, 2 parts dry sediment to 1½ parts 'Stellon' powder. (Commencing with this step, the process is continuous and must be carried to completion once begun.)

(4) Add 'Stellon' liquid to a slight excess of liquid over powder and spatulate for 25 sec and no longer.

(5) Pour mixed sediment slurry into the wire mould and then spatulate it slightly to even out any grain accumulation. The slurry will commence polymerization immediately (at a room temperature of 68° F ± 10°) and will be completely hardened in 1 h. It is most important that the slurry is not disturbed or moved during the hardening period.

(6) Remove the hardened wafer by tapping the wire frame with the spatula handle and mark sample number on rough surface of wafer with waterproof Indian-ink.

(7) Using 500 grit grinding powder, grind down the smooth side of the wafer until an adequate surface has been cut into the grains. (It is important that the wafer be ground sufficiently to provide a representative plane, or slice, through the artificial rock.)

(8) Clean wafer of grit in tap water, taking care not to polish ground side with the drying towel. Simply blot dry.

(9) For mounting, mix in a crucible, 1 part 'Stellon' powder to 1 part 'Stellon' liquid plus a very slight excess liquid. Spatulate for 30 sec. Place 2 drops of 'Stellon' liquid on polished side of wafer. Immediately pour slurry on to frosted side of glass slide. Shake excess liquid from wafer and gently lower wafer on to slide, using care not to entrap air bubbles. Apply pressure to wafer and move it back and forth to remove surplus slurry and any air bubbles. A small weight may be placed on the wafer to hold it firmly during a 1-h cementing period. Mark sample number on the glass slide.

(10) Grind the slide-mounted wafer as would be done with a normal rock. Place slide in water for 10 min and lift the very thin acrylic wafer off and wash it in tap water. At this time, the wafer may be trimmed with a pair of scissors.

(11) Number a clean glass slide with a diamond stylus and attach the thin wafer to it. Position the wafer with a spot of 'Durafix' in one corner.

(12) Place slide on 95° F hot-plate and cover-slip on 130° F hot-plate.

(13) Lift wafer and place a small amount of filtered Canada balsam beneath. Press wafer down and cover with another small portion of balsam. Overlay with cover slip, position and allow slide to cool 1 h. Remove surplus balsam with a hot knife and clean with methyl alcohol.

Slides prepared by the foregoing technique (Fig. 1) are chemically and physically stable; the polymerized polymethyl methacrylate does not discolour with time or with changes in temperature. We have made petrographic slides of unconsolidated sediments which ranged in size from argillaceous silts to mixtures of coarse sand and pebbles. The optical properties of the various minerals are in no way altered or obliterated. The refractive index of 'Stellon' is slightly less than that of quartz, and we suggest that the refractive index be checked for

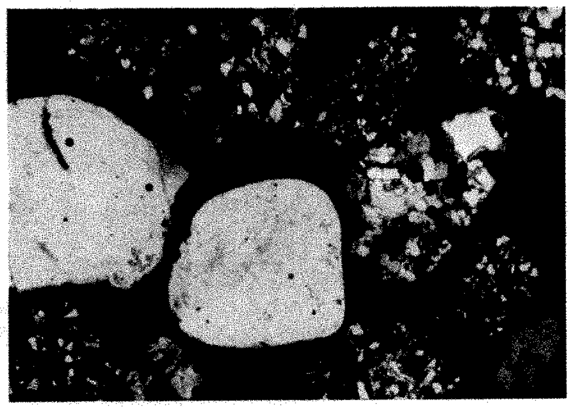


Fig. 1. Photomicrograph of lithic-quartz sand from Cardigan Bay, about two miles south-west of Borth. Note that the types are readily determined as a mixture of arenite and vacuole quartz grains. The large quartz grain in centre field is about 1 mm in diameter (crossed nicols)

each new batch of 'Stellon' in case of slight changes in compounding by the manufacturer.

This technique has been developed during the course of research into the composition of Irish Sea sediments. The investigation is directed by Prof. Alan Wood and is supported by a grant from the Department of Scientific and Industrial Research.

A New Fossil (*Papillomembrana* sp.) from the Upper Precambrian of Norway

A new fossil was recently found during investigations of the rocks of the Sparagmite group in Southern Norway.

The body of the fossil has a thin outer membrane, which, in thin section, is opaque; presumably the substance is carbonaceous. Its most conspicuous features are the dense papilla-like protuberances of the membrane. They are thin-walled, hollow and about 40–45μ long and 8–10μ thick. They are usually somewhat swollen at their apices, and some carry hooks and small spines. The bases are generally expanded, and the voids of the protuberances seem to open into the body cavity.

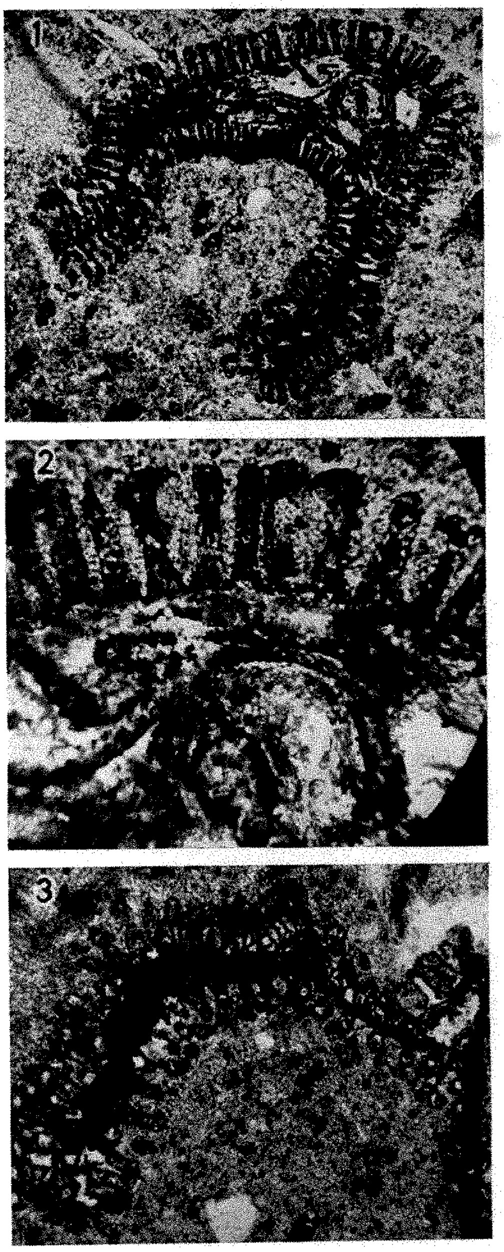
In the two best preserved specimens (Figs. 1 and 2), structures are visible in the interior of the body which appear to be a detached, irregularly folded membrane. Besides this membrane, there are irregular lumps of a yellowish-brown substance, presumably organic. This substance is not found outside the fossil. The original shape of the fossil is not known; all five specimens that have been observed are compressed. The sections indicate that it could have been cylindrical or spherical, and about 0·4–0·5 mm in diam. The fossil has been named *Papillomembrana compta* gen. nov. sp. n.

The affinities of the fossil are uncertain. It has a rather complex structure, considering its great age; similar structures, so far as I know, have not been reported from such old beds before.

Papillomembrana has some superficial resemblance to the dasycladacean algae. The body cavity might correspond to the thallus, and the papillæ to the primary branches. Most dasycladaceans are incrusted with lime, but specimens with a carbonaceous skeleton are known. *Papillomembrana* is only slightly smaller than *Vermiporella* and other small dasycladaceans. The internal structures are, however, different from anything found in this group and recall an organism with a double wall. Much further work is necessary to ascertain the systematic position of *Papillomembrana*.

In addition to the specimens of *Papillomembrana*, there are some other less well-defined fossils in the same rock. They consist of thin-shelled, hollow carbonaceous spherical bodies with a diameter of 25–100μ, and thin carbonaceous films which in some cases have spines and other outgrowths on their upper side. These spines are, however, considerably smaller than those *Papillomembrana*. They resemble some of the structures described and named by Timofeev from beds of 'early' Precambrian age[1].

The fossils are found in a black mudstone pebble in the basal part of the Biri Conglomerate Member of the Brøttum Formation. This formation, which is the oldest one in the Sparagmite Group, is of Esmarkian age ('earliest' Precambrian). The mudstone, which is highly carbonaceous and remarkably free of clastic material coarser than clay, is found as rare pebbles in the typical section of the conglomerate along road 50 at the western side of Biskopåsen in Ringsaker (120 km north of Oslo).



Figs. 1–3. *Papillomembrana compta* gen. nov., sp. n. (1) The holotype, median section (× c. 104). (2) Detail of the holotype, showing the papillæ, and part of the structures in the interior (× c. 385). (3) A completely compressed specimen, showing hollow papillæ. All figures from a thin section of a pebble in the Biri Conglomerate member of the Brøttum Formation (Esmarkian) at Biskopåsen, Ringsaker. The specimens belong to Paleontologisk Museum, Oslo, Reg. No. 73173

The stratigraphy and general geology of the area are described, and references given by Holtedahl[2]. The stratigraphic position of the various units of the Sparagmite group is shown in Table 1.

Table 1

Chronostratigraphical units		Lithostratigraphical units	
Cambrian	1 *a*	(Fossiliferous shales, etc.)	
	Eo– Cambrian	Ringsaker Quartzite formation Vardal Sparagmite formation Ekre Shale formation Moelv Congl. (tillite) formation Moelv Sparagmite formation	Sparagmite group
Precambrian	Esmarkian	Biri formation (dark shales with limestone members) Brøttum formation (greywackes and dark shales with conglomerates and shale—limestone members in the upper part) (base unknown)	
	(Riphean 800–900 million y.)	Crystalline basement complex	

The imbrication of the pebbles found in some beds of the Biri Conglomerate indicate a transport from a southerly direction. The pebbles of unmetamorphic sediments are concentrated in the basal part of the conglomerate. It might be assumed that when the relief was sharpened by a slight movement along the fault lines bordering the Sparagmite basin, the sediments on the outer margins of the basin were eroded and deposited at the base of the conglomerate. It can therefore be assumed that the mudstones in which *Papillomembrana* are found correspond to the lower part of the Brøttum Formation, as its lateral facies outside the basin proper, or that they correspond to Esmarkian beds older than the Brøttum Formation. At present, Cambrian beds rest directly on the Precambrian crystalline basement to the south of the Sparagmite basin, and all traces of the mudstones and other Esmarkian rocks were therefore probably removed by erosion prior to the deposition of the Cambrian. Radioisotope age of the Precambrian basement farther south[3] indicate that it is comparatively young, 8–900 million years, and these give a probable maximum age for *Papillomembrana*.

I thank Prof. O. Holtedahl, Prof. O. A. Høeg and Dr. S. Manum for discussions about these fossils. It was Prof. O. Holtedahl who, in 1943, encouraged me—then a very young student—to look for fossils in the Sparagmite group.

CRYSTALLOGRAPHY

Structure of 10,10-Dibromoanthrone

As part of a programme devoted to the examination of electron lability in various classes of organic compounds, we have determined the crystal and molecular structure of a halogen derivative of anthrone: 10,10-dibromoanthrone.

The compound was prepared by the reaction of bromine with anthrone in carbon disulphide. The crystalline reaction products appear as light lemon-coloured rods having a rhombus-shaped cross-section. They are not stable in air at room temperature for extended periods. However, they do keep well under refrigeration, and we have been able to draw excellent crystals from a batch kept in the refrigerator over a 12-month period.

Two specimens were used for the collection of the data. They were very much alike in shape and size having lengths along the rod axis of about 0·6 mm. and an average cross-sectional 'diameter' of about 0·1 mm. $h0l$ and $0kl$ data were obtained from one crystal using molybdenum radiation on the precession camera. The other crystal was used for multiple-film equi-inclination Weissenberg photographs (copper $K\alpha$-radiation) of levels $l = 0$ to $l = 10$. About 49 per cent (1,122 out of 2,297 possible) of the available reflexions were recorded on film, and intensities were measured by visual comparison with a graded standard. Lorentz and polarization factors were applied to all of the data, and in addition, the Weissenberg data were corrected for absorption effects. The various sets of Weissenberg data were scaled together using commonly occurring reflexions observed on the precession camera films.

The unit cell was found to be monoclinic (b-axis unique) with $a = 9{\cdot}09 \pm 0{\cdot}02$ Å, $b = 10{\cdot}52 \pm 0{\cdot}03$ Å, $c = 15{\cdot}64 \pm 0{\cdot}04$ Å and $\beta = 125° \; 10' \pm 5'$. The observed symmetry extinctions give unambiguous assignments of space group $P\,2_1/c$, No. 14. The density calculated for $Z = 4$ is 1·91 g/c.c. and that determined in n-heptane with the Berman balance is 2·00 g/c.c. Linear absorption coefficients for copper $K\alpha$- and molybdenum $K\alpha$-radiation are 90·486 cm.$^{-1}$ and 75·44 cm.$^{-1}$ respectively.

A three-dimensional 'cold-atom' Patterson function was calculated, and analysis of Harker-related bromine–bromine interactions led to location of the heavy atoms.

Three least-squares refinement cycles were made on the bromine positions using the set of 485 of the strongest reflexions. The R-factor dropped to 26 per cent and a 3-D Fourier was calculated using bromine phases only. Of the fourteen carbon atoms and one oxygen atom omitted from the structure factor calculations, eleven carbon atoms and the oxygen atom appeared clearly in the Fourier as well as the bromine atoms. The positions of the three missing carbon atoms were postulated from chemical considerations and the resulting seventeen-atom structure refined rapidly in four cycles from 32 to 14 per cent. Structure factors and least-squares refinement were computed now for 1,122 observed reflexions and in three cycles the R-factor dropped from 40 to 17·5 per cent. Individual isotropic temperature factors for all atoms were varied for all refinement cycles which included the complete contents of the asymmetric unit. Table 1 lists fractional co-ordinates and temperature parameters for a complete molecule. Fig. 1 is a crude sketch of the structure viewed along c. The circles represent bromine atoms and the long lines represent the carbon planes seen edge-on. Fig. 2 is a drawing of the structure projected on to (010).

Our earliest conceptions of the conformation of this molecule were based, in large part, on the stereochemistry of a molecule built of model atoms designed to exhibit correct van der Waals' volumes. In such a model, the anthrone system assumed a puckered form. In contrast, our results show that the ring system is close to being planar. The sum of the bond angles about the carbonyl

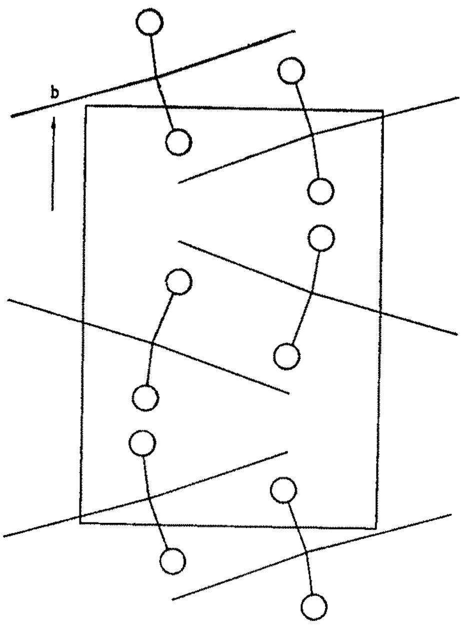

Fig 1 View of the structure along the c-axis

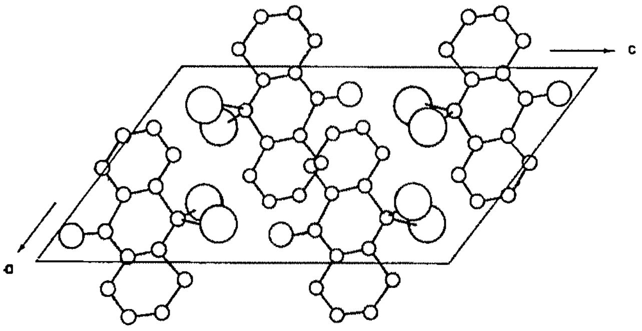

Fig 2 Projection of the structure on to (010)

carbon atom is 359 9°, and the sums of the bond angles about the carbon atoms which are shared by ring systems are 359 7°, 358 9°, 356 3° and 359 9°

The plane containing the bromine atoms and the tetrahedral carbon atom to which they are bonded is approximately perpendicular to the plane containing the tetrahedral carbon atom and the two carbon atoms in the ortho positions in the centre ring The angle between the two planes is 92 1° Our first model also implied that the bromine atoms were placed unsymmetrically above and below the ring system The calculated interatomic distances between the bromine atoms and the carbon atom para to the tetrahedral carbon atom are 4 384 Å and 4 475 Å Accordingly, the molecular structure is a close approximation to that produced by two intersecting mirror planes One of these contains the ring system The other contains the two bromine atoms and the carbon atom to which they are bonded

The intramolecular bromine–bromine distance is 3 169 Å, in very close agreement with the value of 3 17 Å found in CBr_4[1]. The shortest intermolecular bromine–bromine distance is 4 203 Å The closest intermolecular carbon–carbon distance is 3·556 Å Unusual carbon–carbon distances of 1 610 Å and 1 575 Å are found between C_{13}–C_{17} and C_{12}–C_{16} respectively Also there are some short carbon–carbon distances of 1 238 Å, 1 310 Å, 1 296 Å and 1 326 Å in the ring systems Fourier and difference Fourier syntheses indicate anisotropy in the thermal motion of the atoms, and the decision as to the validity of these distances will depend on least squares refinement using anisotropic thermal parameters

The molecular packing leaves infinite channels extending in the *a* direction between the parallel planes of centro-symmetrically related molecules There do not appear to be any discrete large holes or cavities in the structure

We thank Miss A Pauline Krukonis for estimation of the 3-*D* intensity data and Dr T Mukherjee for preparation of this compound

CHEMISTRY

Preparation of Very High Specific Activity Iododeoxyuridine, Iodouridine and Iodouracil, labelled with Iodine-125, -131 or -132

As part of a contribution to a study of the relative merits of radioactive substances used for brain tumour[1] localization we were asked to prepare ^{131}I-5-iododeoxyuridine of very high specific activity (of the order of 100 µc./µg) and in a solution suitable for injection into rats

Two methods of synthesizing the unlabelled compound have been reported by Prusoff[2] In the first of these, equal weights of deoxyuridine and iodine are refluxed together with chloroform and nitric acid, and the product is separated by crystallization This method was successfully used to prepare ^{131}I-labelled samples of low specific activity, using many milligrams of iodine carrier In the second method, equal weights of deoxyuridine and iodine are heated in a solution of sodium hydroxide, and the product is separated from the reactants by elution from an anion-exchange column with 0 1 N formic acid This method was also utilized in preparing low specific activity samples, but the resulting solutions were too toxic to be used *in vivo*

There are obvious practical limitations to the specific activity which may be achieved if the product is to be isolated by crystallization, so we first sought an alternative method of isolation Using approximately 4 mg each of deoxyuridine and low specific activity iododeoxyuridine (prepared by the first of the methods outlined here and purified by several recrystallizations from hot water) dissolved in 2 ml of 0 1 N sodium hydroxide, we found that the two compounds could be separated from one another by elution from an anion-exchange column with 0 01 M citric acid The column was of 'Amberlite *CG*-400 resin', 100–200 mesh, previously conditioned with 0 1 M hydrochloric acid and washed with water, its dimensions were 22 cm × 0 5 cm diam

The elution curve so obtained is shown in Fig 1*a* The two compounds were identified by their ultra-violet absorption spectra (deoxyuridine has an absorption peak at 262 mµ and iododeoxyuridine at 288 mµ, in 0 01 M citric acid) and the iodinated compound by its activity measured in a well-type scintillation counter The eluate containing the iododeoxyuridine was itself suitable for use *in vivo*, but if required could readily be buffered and made isotonic with normal saline by adding the appropriate weights of sodium phosphate and sodium citrate

In order to attain the required high specific activity we next carried out the iodination with carrier-free ^{131}I-iodide, so that the specific activity of the product would be limited only by the presence of traces of inactive iodine contaminating the reactants or the glassware which were used This was achieved by refluxing together 16 mg deoxyuridine, 0 4 ml 1 N nitric acid, 0 2 ml chloroform,

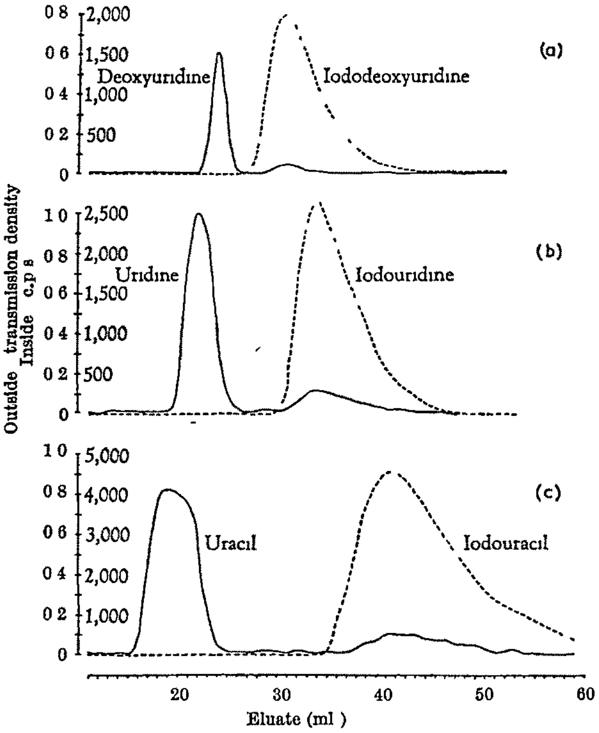

Fig 1 Elution of (*a*) deoxyuridine and ^{131}I-5-iododeoxyuridine, (*b*) uridine and ^{131}I-5-iodouridine, and (*c*) uracil and ^{131}I-5-iodouracil from column of 'Amberlite *CG*-400' resin with 0 01 M citric acid at room temperature - - - -, Activity, ——, transmission density at 262 mμ

and 0 1 ml carrier-free ^{131}I-iodide solution containing about 2 5 mc iodine-131 (This solution was supplied by the Radiochemical Centre, Amersham, Code *IBS*–3, and was essentially 0 02 N sodium hydroxide) After refluxing for 2 h on a water-bath, the aqueous phase was separated, made just alkaline with 0 5 M sodium hydroxide, and placed on an anion-exchange column prepared as described here The column was washed with 35 ml 0 01 sodium hydroxide, which carried off less than 1 per cent of the initial ^{131}I-iodine activity, presumably that which was still present as iodide

On eluting with 0 01 M citric acid, the deoxyuridine was first removed and identified as before Next, at the stage at which iododeoxyuridine was expected to be eluted, about 50 per cent of the iodine-131, measured this time by means of a re-entrant ionization chamber, came off the column in a single peak in some 10 ml of eluate No inactive iododeoxyuridine could be detected by ultra-violet absorption spectrometry, the detection limit being about 1 μg/ml The specific activity of the iodinated product was thus at least 100 μc /μg (probably in fact much higher) while the specific activity of the eluted solution was more than 100 μc /ml This was adequate for the subsequent *in vivo* studies, but samples of higher specific activity could obviously be obtained by collecting only the fractions under the peak of the elution curve, or by using more ^{131}I-iodide in the synthesis The ^{131}I-iodine which remained after elution with citric acid was believed to be present in a high oxidation state, being only removed from the column with difficulty As a check on the identity of the ^{131}I-iodinated product, in a later experiment we spiked the reaction mixture with inactive iododeoxyuridine just before starting to separate the products The activity peak in the elution curve then corresponded exactly with the peak for ultra-violet absorption at 288 mμ

Attempts to carry out the iodination under alkaline conditions, as in the second of the methods reported by Prusoff, were completely unsuccessful with carrier-free iodine, none of the activity being eluted from the anion-exchange column by citric acid

Prusoff, Holmes and Welch[3] have described syntheses of low specific activity ^{131}I-5-iodouridine and ^{131}I-5-iodouracil We have also prepared these compounds, but in high specific activity, using the method described here for iododeoxyuridine Calibration elution curves for the separation of uridine from iodouridine, and of uracil from iodouracil, are shown in Fig 1, curves *b* and *c* For these two iodinated compounds, as for ^{131}I-5-iododeoxyuridine, the specific activity attainable is limited only by the presence of traces of inactive iodine in the reactants or on glassware, and by the quantity of ^{131}I-iodine which can conveniently be handled

Myers and Vanderleeden[4] have shown that for many biological studies the physical properties of iodine-125 make it more attractive than iodine-131 as a radioactive tracer With this in mind, we have used the iodination and separation methods already described to prepare ^{125}I-labelled iodouracil, iodouridine and iododeoxyuridine Since at present iodine-125 is not available in carrier-free form, each product was necessarily of relatively low specific activity, but because of the longer half-life of iodine-125 (57 4 d, compared with 8 05 d for iodine-131) the shelf-life was also longer In contrast, carrier-free iodine-132 (half-life 2 3 h) may readily be obtained (by milking its parent tellurium-132 supplied in suitable form by the Radiochemical Centre, Amersham, Code *TMC* 1) We have been able to prepare the same iodinated compounds labelled with this isotope, again in high specific activity, using the same methods as before but reducing the refluxing time to 30 min

It is worth noting that carrier-free ^{131}I-iodine has also been used recently by Reith and Tampion[5] in preparing very high specific activity samples of ^{131}I-labelled tyrosines

The samples of iodine-131 and iodine-132 (tellurium-132) used in our work were obtained from the Radiochemical Centre, Amersham; the iodine-125 was made on the Medical Research Council cyclotron, but may also be obtained from the Radiochemical Centre The deoxyuridine, uridine and uracil were obtained from L Light and Co , Ltd

We wish to thank the director of the Medical Research Council Cyclotron Unit, Mr D D Vonberg, for his interest and for permission to publish this work

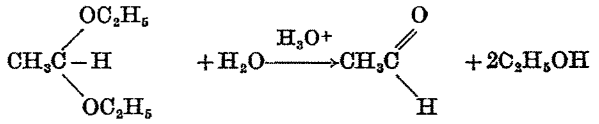
Radiation-induced Hydrolysis of Acetal: Evidence for the Reaction of H_3O^+ Ions in Spurs in the Radiolysis of Water

IT has recently been experimentally demonstrated that in water close to *p*H 7 (ref 1) and at *p*H 4 (ref 2), the reducing radical formed during radiolysis bears a unit negative charge. This suggests that an ejected electron escapes from its parent H_2O^+ ion It follows that H_2O^+ ions should temporarily exist in a spur The H_2O^+ ions, or their hydrolysis products, $H_3O^+(H_2O^+ + H_2O \rightarrow H_3O^+ + OH)$, might cause a suitable solute to 'see' a spur as a volume which temporarily has a lower *p*H than the body of the solution The purpose of this communication is to present some experimental results which we interpret as evidence for this effect

We have irradiated aerated aqueous solutions of diethyl acetal with 50-kVp X-rays A brief description of the thermal hydrolysis of acetal will explain our choice of solute. Acetal is stable in solutions of $pH \geq 7$. It is extremely sensitive to hydrolysis catalysed by H_3O^+ but not by undissociated acid molecules[3], for example undissociated acetic acid. The hydrolysis kinetics are first order with respect to H_3O^+ and acetal. Acetaldehyde (AcH) and ethanol are formed.



$$CH_3C(OC_2H_5)_2H + H_2O \xrightarrow{H_3O^+} CH_3C(=O)H + 2C_2H_5OH$$

Solutions were buffered at *p*H 7 using a potassium dihydrogen phosphate–sodium hydroxide buffer. The Fricke dosimeter, using $G(Fe^{+3}) = 14·5$ for 50-kVp X-rays, was utilized for dose-rate measurements. After irradiation it was observed that acetaldehyde and ethanol had been formed. Acetaldehyde and ethanol were identified by their retention times on a 2·5 m gas chromatographic column packed with a mixture of 40 g of diglycerol on 100 g of ground firebrick. The diglycerol retained 0·5 ml samples of water while the hydrolysis products and acetal were eluted by a flow of nitrogen. Acetaldehyde was also identified by its broad absorption peak at 2750 Å (ethanol and acetal do not absorb at this wave-length and a blank compensated for the small absorption of potassium dihydrogen phosphate). Quantitative analysis for acetaldehyde was carried out by measuring the optical absorption of irradiated solutions at 2750 Å, using an extinction coefficient of 8·5 l mole^{-1} cm^{-1}. The amount of acetal remaining after irradiation was then determined by completely hydrolysing the solution by adding a few drops of concentrated sulphuric acid and measuring the total acetaldehyde thus formed.

For doses up to about 5×10^{23} eV l^{-1} and at an initial acetal concentration of 0·14 moles l^{-1}, *G*(AcH) was constant and equal to *G*(–acetal) within 10 per cent. Beyond this dose, oxidation of ethanol and reduction of acetaldehyde became too significant to permit interpretation of the results. *G*(ethanol) was not determined. A plot of *G*(AcH) against initial acetal concentration increased from the origin and became constant at $G(\text{AcH}) = 2·0 \pm 0·2$ and at an initial acetal concentration equal to 4×10^{-2} molar (Fig. 1). These results refer only to irradiations of less than 5×10^{23} eV l^{-1} dose. Neutral buffered solutions, irradiated at a dose rate of $4·5 \times 10^{19}$ eV l^{-1} sec^{-1}, formed acetaldehyde at a rate comparable with that observed in thermal hydrolysis at *p*H 4. When solutions ($pH \sim 6·8$) were not buffered, an unirradiated solution hydrolysed to a small extent, but radiolysis produced much more acetaldehyde in the same period of time.

These results are interpreted as hydrolysis catalysed by H_3O^+ ions formed in spurs, in competition with both neutralization of H_3O^+ and dilution of H_3O^+ by spur expansion. We assume the rate constant for attack by a proton on an acetal molecule to form an ion-molecule to be at least 10^9 l mole^{-1} sec^{-1} because this type of reaction is usually diffusion controlled. If this were true, acetal would be easily capable of reacting with H_3O^+ during the early stages of the lifetime of the spur. Admittedly, a gap exists in our argument since we must assume that the next stage in the hydrolysis reaction proceeds at a considerably greater rate than deprotonation.

In a spur, $G(H_3O^+)$ should equal *G*(OH). Based on an estimated average initial linear energy transfer in the solution of 0·15 eV/Å, *G*(OH) for neutral water should be between 1·4 and 2·0 (refs. 4 and 5). Decomposition of the ion-molecule formed from H_3O^+ and acetal should be a relatively slow step compared with spur expansion due to diffusion. Thus the charge distribution in the spur should approach that in the body of the solution during the time required for one acetal molecule to hydrolyse. It is therefore not unreasonable that one H_3O^+ ion only catalyses, on the average, the decomposition of about one acetal molecule, that is, that *G*(AcH) is of the same magnitude as $G(H_3O^+)$.

If a free radical mechanism were operative, one would expect *G*(AcH) to reach a limiting value at a much lower initial concentration of acetal than observed. For example, most solutes scavenge the radical yield of H and OH and start to compete for precursors of H_2 and H_2O_2 at about 10^{-6} molar (ref. 6).

For an irradiated solution to have an 'apparent *p*H' of four, the *p*H in a spur must be much lower. In a 0·04 molar acetal solution, a spherical volume with a radius of 30 Å contains three acetal molecules. If a spur of the same volume contained three H_3O^+ ions, the *p*H in the spur would be 1·4.

We believe this is the first time a reaction in radiation chemistry has been interpreted as hydrolysis catalysed by H_3O^+ ions formed during the primary radiolytic processes in water. However, observations have been made by others in the radiolysis of carbohydrate solutions which might be explained by acid-catalysed hydrolysis. For example, radiolysis of dextran solutions yields products which can also be produced by thermal, acid-catalysed hydrolysis[7]. Radiolysis of aqueous ethyl acetate solutions has also yielded the hydrolysis products ethanol and acetic acid[8].

It is possible that a *p*H effect such as we have described contributes to biological damage caused by ionizing radiation.

Action of Polar Reagents on Nylon 66

VARIOUS workers have reported on the action of lithium bromide and similar salts on simple amides and fibrous proteins and have offered contrary explanations as to the mechanism of interaction; it is therefore instructive to consider the effect of these reagents on polyamides.

In the investigation recorded here, nylon 66 films, *c.* 10µ thick and partially oriented by cold drawing, and nylon 66

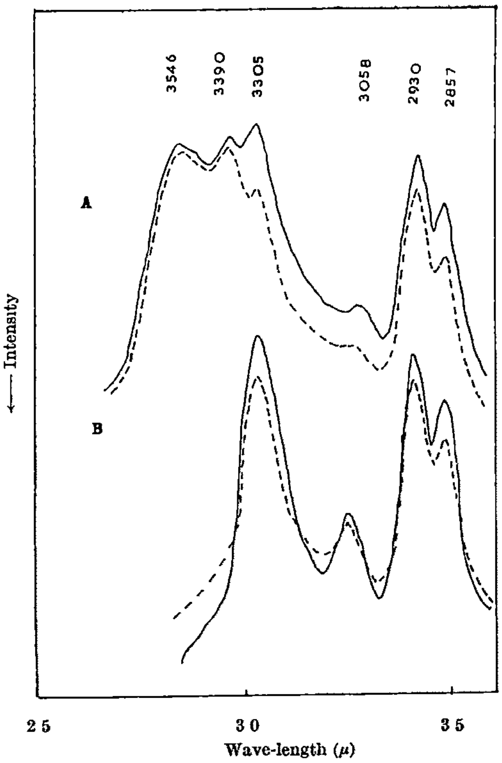

Fig 1 Infra-red spectra of nylon 66 *A*, Treated in magnesium perchlorate, 80° C, 12 h, *B*, untreated film – – –, Parallel, ——, perpendicular to direction of stretching

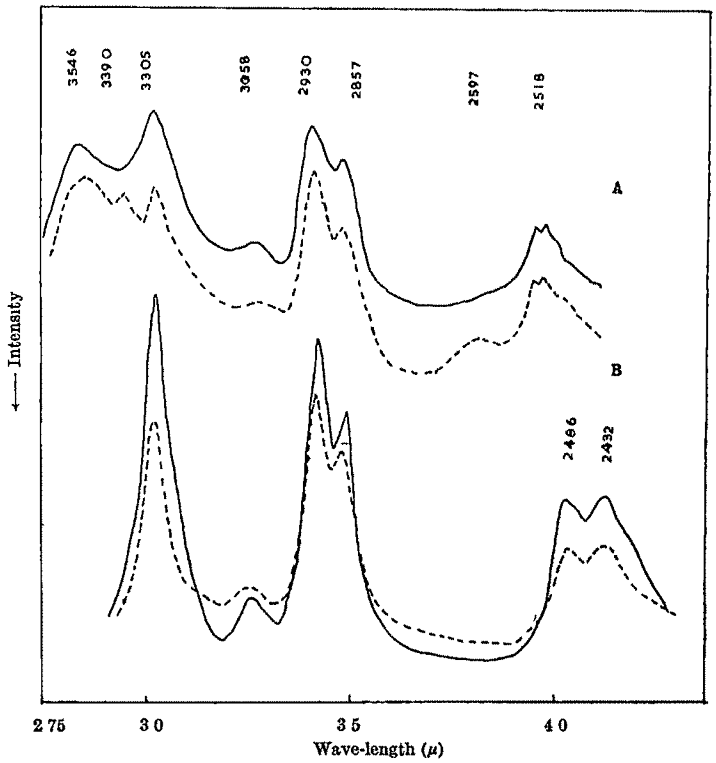

Fig 2 Infra-red spectra of nylon-66 *A*, Treated in magnesium perchlorate, and deuterated, *B*, untreated film, deuterated – – –, Parallel, ——, perpendicular to direction of stretching

filaments, 7 5 denier, commercially drawn, were treated with aqueous solutions of lithium bromide (100 g/100 ml water), magnesium perchlorate (100 g/100 ml water) and lithium perchlorate (50 g/100 ml water) for 12–24 h at temperatures ranging from 20° to 100° C Deuteration was carried out by exposing the films to deuterium oxide vapour at 20° C The films were examined on a Grubb Parsons double-beam infra-red spectrometer, using polarized radiation, and the X-ray diffraction patterns and stress-strain behaviour of the filaments were examined Auxiliary experiments were carried out to study the effect of the reagents on polyacrylonitrile fibres and on *N*-ethylacetamide, and the effect of antimony trichloride on nylon 66

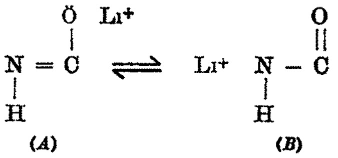
The spectral evidence is illustrated in Figs 1 and 2 A strong interaction between the polar reagents and the peptide group is indicated a new peak appears at 3,390 cm^{-1} and, apart from the broadening of amide bands in the 1,400–1,600 cm^{-1} region, no significant change in spectra is noticed On deuteration, the 3,390 cm^{-1} peak disappears and a band appears at 2,518 cm^{-1} Keeping in view the results obtained by other workers[1–4], it is suggested that the peak at 3,390 cm^{-1} is a new N–H band, for the following reasons·

(1) With the appearance of the new band, the intensity of the original N–H band at 3,300 cm^{-1} gradually diminishes

(2) X-ray evidence is that the interaction is confined to the less-crystalline regions, and this is confirmed by the spectral changes when the treated films are deuterated The broad band due to free water molecules and the new peak disappear rapidly compared with the residual peak at 3,300 cm^{-1}, but on re-hydrogenation the O–D band disappears even during the scanning period while little change is noted in the 2,518 cm^{-1} band this indicates that the peak at 3,390 cm^{-1} is probably not a simple O–H one

(3) The new peak shows slight parallel dichroism and this does not favour its being due to sorbed water

Considering the two possible resonance structures of the peptide group[5]



$$\underset{\underset{H}{|}}{N} = \overset{\overset{\ddot{O}\;\; Li^+}{|}}{C} \rightleftharpoons Li^+ \;\; \underset{\underset{H}{|}}{N} - \overset{\overset{O}{\|}}{C}$$

(*A*) (*B*)

and assuming that a consistent part is played by the ions in an ion-dipole interaction, one may reason out the most probable configuration of electrophilic ions with respect to the ligand[6]

(1) The marked change in the 3μ region (NH stretching mode) and the absence of change in the amide I band (essentially the $C=O$ stretching vibration[7]) do not favour co-ordination as in (*A*) It may be objected that the broadening of the amide bands in the presence of water[4] would mask any effects in this region, but when nylon 66 is dissolved in molten antimony trichloride, the presence of an N–H peak at 3,400 cm^{-1}, amide I band at 1,680 cm^{-1} and amide II band at 1,605 cm^{-1} indicates that reagents which attack $C=O$ groups[1] can bring about a more radical change in the spectrum than is reported here We suggest that degradation of molecular chains, resulting in a large number of $CONH_2$ groups, may be responsible for these changes in the amide I and II bands

(2) Polyacrylonitrile fibres dissolve in aqueous solutions of magnesium perchlorate and lithium bromide one would think that the ions would interact with the cyanide groups and, therefore, that the nitrogen atom would play an important part

(3) Co-ordination through the nitrogen atom, as shown in (*B*), generally results in lowering of the N–H stretching frequency[8], unless the ligand is highly associated by hydrogen bonding, when the frequency may be raised[9] Hence the increased frequency observed here may well result from an ionic interaction as shown in (*B*)

(4) Nylon filaments treated in the foregoing aqueous solutions show a definite decrease in initial modulus and insignificant molecular glide prior to rupture, when stretched If greater rotational freedom is imparted to the

chains by the single-bonded (B) structure, there will be a decrease in the initial modulus[10] and at the same time a closer alignment of the polyethylenic segments will be possible and this will eliminate the gliding of molecules

(5) When lithium bromide is dissolved in N-ethylacetamide there is some sharpening of the broad band in the nuclear magnetic resonance spectrum, although the viscosity of the solution is higher than that of the pure solvent This may be attributed, very tentatively, to a decrease in the effective delocalization of the lone-pair electrons of the nitrogen atom[11]

It is concluded that the probability of an ion-dipole interaction at the nitrogen atom[9,12] in polyamides, when they are treated with polar reagents, may not be ruled out

Reaction Kinetics of the Atomic Oxygen-Graphite System

A RECENT communication by Marsh *et al* [1] reported the existence of a small activation energy for the reaction of graphitic carbon with atomic oxygen at temperatures below 350° C Investigations carried out in this laboratory provide a quantitative measure of the activation energy and suggest reasons for the poor agreement with earlier reports[2,3] which indicate a zero activation energy

The high-frequency electrodeless discharge system used in these studies consisted of a 13 56 Mc/s oscillator capable of supplying 250 W to the gas and a 4-cm diameter borosilicate glass reaction tube[4] Oxygen was admitted to the system at a rate of 30 c c /min S T.P and maintained at a pressure of 1 3 mm mercury The rate investigation used spectroscopic grade graphite rods (National Carbon Co , No 3829) 6 4 mm long and 6 1 mm in diameter, with pyrolytic carbon and activated charcoal used in supplementary experiments The oxidation rate was determined from the loss in weight of the carbon rod after a 15-min exposure to the oxygen plasma

As the oxidation of carbon with oxygen is a surface reaction, the temperature at the surface of the specimen is considered to be the significant parameter This temperature was obtained from measurements of the infra-red radiation in the 1 2–2 5μ range emitted from the carbon rods The temperature measuring device, consisting of an optical telescope, a Ge filter, and PbS semiconductor detector (Infrascope Radiation Thermometer, Applied Systems Corp , Palo Alto, Calif , 1963), was calibrated with a source of known temperature and similar emissivity

The relationship between oxidation rate and surface temperature over the range 215°–300° C for a graphite rod immersed in the plasma is shown in Fig 1 The Arrhenius equation, $k = Ce^{-E_a/RT}$, fits the data well and yields a value of 6 5 kcal/mole as the activation energy, E_a A major source of heat is the exothermic oxidation reaction As the average sample temperature, which is considerably lower than the surface temperature, does not increase in direct proportion to surface temperature, use of the average sample temperature will lead to a low value of the activation energy

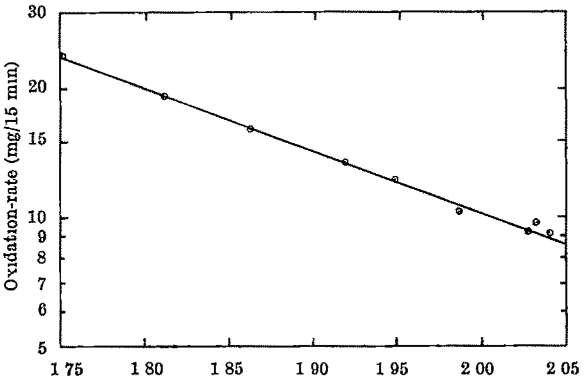

Fig 1 Oxidation rate of spectroscopic grade graphite rods in electrically activated oxygen as a function of surface temperature

Several other factors strongly affect activation energy. Metallic impurities are known to lower the requisite activation energy[5] and increase the oxidation rate of graphite[6] For example, the measured activation energy of a spectroscopic graphite rod wetted with 0 01 N cupric chloride is 12 per cent lower than that of a pure rod Preliminary experiments indicate that in addition to neutral atomic oxygen (3_{P_g} and 1_{D_g}) ionic species such as $O_2+(2_{\pi_g})$ and negatively charged species of oxygen also contribute to the overall reaction rate in the radiofrequency excited plasma Applying a d c potential of -25 V to the carbon specimen reduces oxidation rate to 50 per cent of the rate of a comparable sample at 0 to $+200$ V d c Measurements of atomic oxygen concentration made with differential thermocouple recombination probes[7] do not correlate well with the observed oxidation rates The apparent discrepancies in activation energy may be due, in part, to different proportions of active species of oxygen produced by the various discharge systems

Thermal Stability of Polynuclear Aromatic Hydrocarbons and the Polarographic Half-wave Reduction Potential

WE have noted a relation of the thermal stability of certain polynuclear aromatic hydrocarbons to the polarographic half-wave potential In attempting to find some theoretical justification for this relation, it was found that Bergman[1] had related the $E_{1/2}$ to the 'p' ultra-violet band as determined by Clar[2] Also, Basu[3] has related the $E_{1/2}$ to the lowest unoccupied energy orbital Thermal stabilities were determined by Madison[4] by pyrolysis

Table 1 THERMAL STABILITY AND THE $E_{1/2}$, '*p*' BAND FREQUENCY, AND ENERGY OF LOWEST UNOCCUPIED ORBITAL

Compound	Class	$E_{1/2}$ (V[1])	'*p*' Band cm^{-1} (ref 1)	Energy[3] of lowest unoccupied orbital	Moles[4] of gas produced/ moles of charge	Temp (°C)	Time (min)
Naphthalene	I	−1 98	35,090	0 618	2 × 10^{-3}	500	90
Phenanthrene	I	−1 95	34,190	0 605	2 9 × 10^{-3}	500	90

Benz (*a*)-anthracene	I	−1 53	27,860	0 452	22 × 10^{-3}	475	60
Anthracene	I	−1 46	26,700	0 414	37 × 10^{-3}	475	60
Naphthacene	I	−1 135	21,230	0 294	414 × 10^{-3}	475	30
Triphenylene*	—	−1 97	35,210	0 684	2 4 × 10^{-3}	475	60
					6 9 × 10^{-3}	500	90
Pyrene	II	−1 61	29,990	0 445	1 1 × 10^{-3}	475	60
Benz (*a*)-pyrene	II	−1 36	26,010		10 × 10^{-3}	475	50
Biphenyl	III	−2 075	40,000		% decomposed = 0 1 (ref 6)	900°F	60
p-Terphenyl	III	−1 905	36,230		% decomposed = 0 28(ref 6)	900°F	60
Fluorene	IV	−2 65 (ref 5)			133 × 10^{-3}	475†	60
Acenaphthene	IV	−2 58 (ref 5)			128 × 10^{-3}	465†	30

* Note that although triphenylene ought to be related structurally to Group I, its $E_{1/2}$ does not plot linearly with the '*p*' band frequency. It would, however, be valid to compare a triphenylene anellation series

† Note that temperatures and times nullify apparent reversal

followed by mass spectrometric analysis of the gas phase products. Table 1 presents the composite data· there the compounds are grouped into classes on the basis of Bergman's classification The groups have theoretical justification in so far as that compounds of the same class plot linearly with respect to $E_{1/2}$ versus '*p*' band frequency Further, comparisons are valid· (*a*) if the compounds are planar molecules of the same class; and/or (*b*) if the compounds are members of an anellation series (for example, naphthalene, anthracene, naphthacene)

It is interesting to note that "the $E_{1/2}$ for an aromatic hydrocarbon measures the energy required to place one or more electrons in the lowest unoccupied orbital"[1] and that "the first electronically excited state of any polyene is derived from the corresponding ground state by the promotion of one electron from the highest occupied level to the lowest unoccupied level"[7] It would appear, then, that the thermal stability of a polynuclear aromatic hydrocarbon is governed by the energy required to promote electrons to the lowest unoccupied orbitals, and the higher that energy, the most stable the molecule This is further confirmed by the higher frequency and more negative reduction potential.

BIOCHEMISTRY

A Direct Microbiological Assay for Urine Phenylalanine in Phenylketonuric Screening

INCREASED amounts of both phenylalanine and orthohydroxyphenylacetic acid are found in the urine of phenylketonuric (PKU) infants at age 5–8 days, frequently several days before phenylpyruvic acid can be detected in the urine[1]. Determination of these substances in the urine by paper chromatography is not suited to large-scale screening programmes The direct microbiological assay procedure described here is simple enough to be used as a screening test

Direct microbiological assays were used to detect increased amounts of valine, leucine, and isoleucine in urine specimens, dried on filter paper, obtained from mentally retarded children[2] This principle was extended to measurement of phenylalanine in urine specimens collected in a similar manner from infants and mentally retarded children. The standard phenylalanine assay with *Leuconostoc mesenteroides* was utilized together with a commercially prepared media (Difco 'Phenylalanine Assay Broth')[3] As preliminary controls, we used specimens from 100 infants obtained in the Cincinnati PKU testing programme

For each specimen, ½-in paper squares were cut and placed in clean, dry bacteriological culture tubes (13 mm × 100 mm) Uniformity in size of the paper squares from urine or standards was essential to obtain reproducibility of results The culture medium (Difco 'Phenylalanine Assay Broth') was prepared by suspending 5 25 g of dried broth plus 0 0064 g of phenol red in 100 ml. distilled water and heating to boiling as recommended by the manufacturer The addition of phenol red to the media provided a quicker and more accurate method for reading the specimens After 2 ml of the broth was placed in each tube, they were covered with aluminium caps and autoclaved for 15 min at 15 lb pressure, 121° C, and allowed to cool before use Three 10-ml and one 5-ml pipettes and 50 ml of 0 9 per cent saline were sterilized at the same time

Stock solutions of phenylalanine were prepared to contain 20 μg/ml , 40 μg/ml , 120 μg/ml , 200 μg/ml , and 400 μg/ml The standards were also dried on filter paper and ½ in squares cut, placed in tubes and the broth added

Leuconostoc mesenteroides was maintained on Difco 'Yeast Agar' The inoculum was prepared by making a transfer from the agar stab to a tube containing 10 ml Difco 'Micro Inoculum Broth' and incubating for 24 h at 30° C The inoculum was centrifuged for 10 min at medium speed, the cells washed twice in 10 ml sterile saline and resuspended in 5 ml sterile saline Sterile unknowns and standard were inoculated immediately with a loopful of the cell suspension *Leuconostoc mesenteroides* produces acid and the colour of the phenol red indicator changed with increasing amounts of phenylalanine and increasing growth of the bacteria (Table 1)

Table 1

Amount of phenylalanine (μg/ml)	Turbidity	Colour
20	− − −	Red
40	±	Red
80	+	Yellow-orange
120	+ +	Yellow-orange
200	+ + +	Yellow
400	+ + + +	Yellow

Specimens from infants used as controls all gave negative tests for phenylpyruvic acid using ferric chloride Phenylalanine was also measured by paper chromatography in all the specimens from control infants Specimens from 3 of 100 infants were positive at the 80–120 μg/ml. level (microbiological assay), increased amounts of phenylalanine were detected on the paper chromatograms, together with excessive amounts of other amino-acids No other metabolites characteristic of PKU were found

Filter paper specimens obtained from 1,000 mentally retarded children living at home (age 6–18 years) were then tested Seven specimens were positive at the 200–400 μg/ml level Approximately 200 additional specimens were positive in the range 40–120 μg/ml level Confirming tests were carried out on all specimens showing any growth Total amino-acids were determined by two-dimensional chromatography and orthohydroxyphenylacetic acid and phenylalanine by one-dimensional chromatography[4] of urine eluted from the test specimens Table 2 shows the results of the confirming tests on the 7 strongly positive specimens The excretion of other than phenylalanine was in the normal range Orthohydroxyphenylacetic acid was demonstrated in each of the specimens The diagnosis of phenylketonuria was confirmed by determination of serum phenylalanine In 5 of these children, phenylketonuria had not been recognized previously

Table 2 CONFIRMING TESTS ON URINE SPECIMENS SHOWING STRONGLY POSITIVE TEST FOR PHENYLALANINE BY MICROBIOLOGICAL ASSAY

Specimen No	Phenylalanine		Orthohydroxyphenylacetic acid
	Microbiological assay	Paper chromatography*	Paper chromatography*
B-30	+ + + +	350	160
B-30 *A*	+ + + +	280	125
G-18	+ + + +	310	88
L-47	+ + +	200	90
S-9	+ + + +	420	65
T-4	+ + + +	430	90
Y-90	+ + +	230	100

+ + +, 200 μg/ml , + + + +, 400 μg/ml. * μg/ml

The 200 additional specimens were negative for orthohydroxyphenylacetic acid, however, the excretion of phenylalanine was found by paper chromatography within the range determined by microbiological assay Among these specimens the highest value found by chromatography for urine phenylalanine was 100 μg/ml There appeared to be a positive correlation between elevated urine phenylalanine in the range 70–110 μg/ml and generalized mild aminoaciduria

Approximately 95 per cent of non-phenylketonuric children excreted less than 73 μg/ml[5] The minimum phenylalanine excretion observed in 44 untreated phenylketonuric patients was 100 μg/ml In this work 10 per cent of the urine specimens from retarded children were retested because of phenylalanine concentration over 40 μg/ml. Among these 4 8 per cent contained phenylalanine in the range 70–120 μg/ml and an additional 0 7 per cent contained phenylalanine in excess of 200 μg/ml

The direct microbiological assay for phenylalanine appears to be a simple and rapid screening method for phenylalanine It is useful as a supplementary test for PKU as well as for screening for aminoaciduria

This investigation was supported in part by grant *MH*-01175, National Institute of Health and Neurological and Sensory Disease, Service Project grant No *N*3702A63

Inhibition of Pyridine Nucleotide Transhydrogenase by Dicumarol

WE have recently described the hormonal sensitivity of a transhydrogenase reaction in mitochondria (reaction I)[1].

$$NADPH_2 + AcPyAD \rightarrow NAD + AcPyADH_2 \qquad I$$

Reaction I is stimulated by diethylstilbœstrol and œstradiol and thus differs from the transhydrogenase of Kaplan[2]. This may reflect a difference in the method of preparation which preserves its hormonal sensitivity[3] In further studies of this reaction, the reverse direction (reaction II) has been examined.

$$NADH_2 + NADP \rightarrow NAD + NADPH_2 \qquad II$$

In this report, the inhibitory effect of dicumarol on reactions I and II will be described

The enzyme was prepared as follows Livers were removed from male rats and placed on ice A 10 per cent homogenate (w/v) in 0 25 M sucrose was prepared in a glass homogenizer with a 'Teflon' pestle. After centrifuging for 10 min at 700 *g*, the pellet was discarded and the supernatant centrifuged at 7,000 *g* for 15 min This pellet was washed twice in sucrose, suspended in 0 03 M phosphate (*p*H 7 0), and centrifuged for 20 min at 20,000 *g* The pellet was suspended in phosphate so that 1 ml represented 2 g of liver. The mitochondrial suspension was subjected to ultrasound for 45 sec, an equal volume of phosphate was added and this suspension was centrifuged at 25,000 *g* for 20 min. The supernatant containing mitochondrial fragments was then used in the following experiments

The inhibitory effect of dicumarol on the rate of reaction I is shown in Fig 1 Simultaneous reactions were followed for 5-sec intervals in four cuvettes with a 1-cm light-path at 375 mμ by means of a Gilford model 2000 multiple sample absorbance recorder The reaction mixture contained in a volume of 1 ml , phosphate buffer (*p*H 7 5) 50 μmoles, Mg^{++} 1 μmole, enzyme 10 μl , and where indicated $NADPH_2$ 0 23 μmoles, 3 AcPyAD 0 55 μmoles, and dicumarol 0·1 μmole This concentration of dicumarol (10^{-4} M) was found to be a potent inhibitor of reaction I. A similar effect was seen when $NADPH_2$ was replaced by $NADH_2$. The effect of dicumarol on the reverse reaction (II) was examined As Danielson and Ernster have reported[4], this reaction is accelerated in the presence of Mg^{++} and ATP (Fig 2) The reaction was followed at

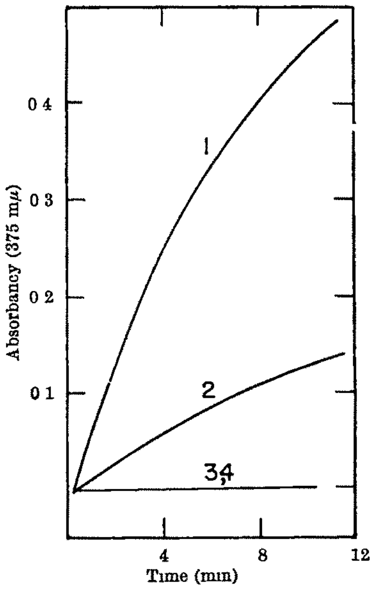

Fig 1 Inhibition of reaction I by dicumarol Four simultaneous reactions were followed sequentially for 5-sec intervals Cuvette 1 contained buffer, $NADPH_2$, AcPyAD, Mg^{++} and enzyme Cuvette 2 contained, in addition to reaction mixture I, dicumarol Cuvette 3 lacked $NADPH_2$, cuvette 4 lacked AcPyAD See text for concentrations of the components

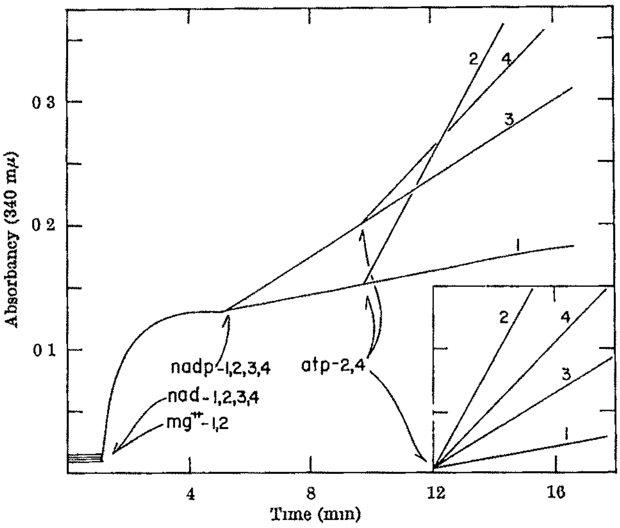

Fig 2 Effect of Mg^{++} and ATP on reaction II Four cuvettes were used as in Fig 1 All cuvettes contained buffer, potassium cyanide, alcohol dehydrogenase, ethanol and enzyme Cuvettes 1 and 2 contained Mg^{++} NAD added to all cuvettes was promptly reduced NADP was added to all cuvettes ATP was added to cuvettes 2 and 4 The rates from the time of ATP addition are shown in the inset to demonstrate their different slopes

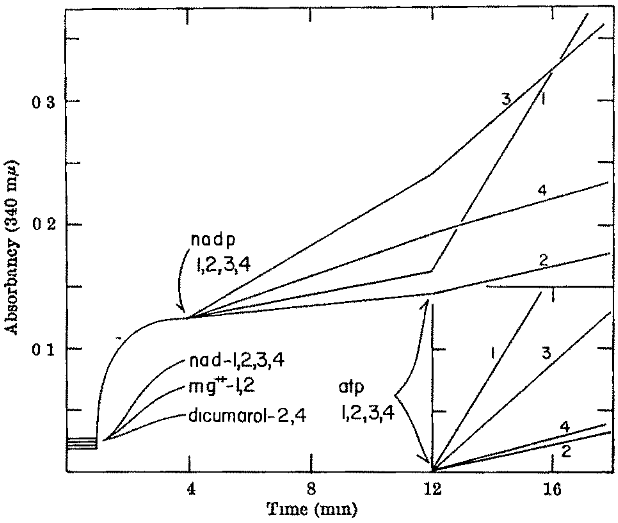

Fig 3 Inhibition of reaction II by dicumarol Four cuvettes were followed as in Fig 1 All cuvettes contained buffer, potassium cyanide, alcohol dehydrogenase and ethanol Cuvettes 1 and 2 contained Mg^{++}, cuvettes 2 and 4 contained dicumarol NAD added to all cuvettes was reduced NADP was added to all cuvettes and at 12 min, ATP was added to all cuvettes The curves from the point of addition of ATP have been placed in the inset to demonstrate the inhibition produced by dicumarol in cuvettes 2 and 4

340 mμ in cuvettes with a light-path of 1 cm which contained in a volume of 1 ml, *tris* buffer (*p*H 8) 50 μmoles, sucrose 250 μmoles, yeast alcohol dehydrogenase 0 33 mg, potassium cyanide 1 μmole, ethanol 5 μl, NAD 0 033 μmoles, NADP 0 23 μmoles, and where indicated Mg^{++} 6 μmoles, dicumarol 0 1 μmole, and ATP 2 μmoles Fig 2 illustrates the stimulatory effect of Mg^{++} and ATP Mg^{++} in the absence of ATP inhibits reaction II while ATP has only a slight effect on the rate in the absence of Mg^{++} The effect of dicumarol on reaction II is shown in Fig 3 It retards the rate of transhydrogenation whether or not Mg^{++} and ATP are present However, the inhibition is best seen after these additions

That both reaction I and reaction II are inhibited by dicumarol supports the suggestion by Hommes and Estabrook[5] that the enzymes catalysing these reactions are similar This suggestion was made on the basis of their sensitivity to triiodothyronine and high-temperature coefficients The sensitivity to dicumarol also suggests a relationship between transhydrogenase and D-T diaphorase This diaphorase, which is located predominantly in the soluble cytoplasm, is found to a small extent (5 per cent) in mitochondria and is inhibited by dicumarol[6] D-T diaphorase was present in the enzyme preparation used in these experiments and, when dichlorophenolindophenol was the acceptor, its reduction using NADH$_2$ (D) and NADPH$_2$ (T) was inhibited by dicumarol D-T diaphorase is inhibited by triiodothyronine[7], which again points to its similarity to the transhydrogenase(s) which triiodothyronine inhibits[5,8] Since D-T diaphorase differs in its intracellular distribution from transhydrogenase and can be prepared free of transhydrogenase activity, it must be considered as a separate enzymatic entity It is conjectured, however, on the basis of their sensitivity to triiodothyronine and dicumarol, that there may be a common component in these three reactions, I, II, and D-T diaphorase

Circular Dichroic Studies of Synthetic Polypeptides

RECENTLY in solutions of α-helical polypeptides and proteins a Cotton effect was observed, having an inflexion point at 225 mμ and which has been shown to be conformation-dependent[1-3] This Cotton effect probably plays a major part in determining the shape of the rotatory dispersion curve in the visible region and therefore is responsible for the Moffitt term, which has been the empirical factor in estimates of the helical contents of polypeptides[4]. We wish to report here a sensitive method for studying the conformation of polypeptides by using the circular dichroism (C D) measurements[10] in the ultra-violet region of this Cotton effect at 225 mμ The surface of the C D bands (a measure of the rotational strength) can be correlated with the amount of helical content, while the sign of C D bands might be related to the absolute conformation, that is, the sense of helix

In order to elucidate the influence of the amino-acid residues on the sense of twist of helix the following L- and D-polypeptides were prepared polypeptides such as poly-glutamic acid, poly-lysine, and poly L- and D-aspartic acid, which in the side-chain contains a chromophore (carboxyl group) beyond the β-carbon[5]

The poly-glutamic acid and poly-L-lysine were prepared according to Idelson *et al*[6] Poly-L-aspartic acid was prepared from poly benzyl-L-aspartate (mol wt = 90,000) debenzylated with anhydrous hydrogen bromide in a mixture of benzene and chloroform Elementary analysis of a sample dried in vacuum at 100° for 16 h gave the proper results of poly aspartic acid In view of the possible formation of β-peptide linkage, one sample was checked following the chemical method of Kovacs *et al.*[7]. The results indicated about 7 per cent of β-peptide linkages. However, ultra-violet analysis showed the absence of succinimide rings and no detectable benzyl groups.

The results shown in Fig. 1 indicate that the helical form of poly-L-glutamic acid (*p*H 4) and of poly-L-lysine (*p*H 11) exhibit a negative circular dichroism curve, whereas the enantiomorph poly-D-glutamic acid in identical conditions yields a positive C.D. curve. Similarly a negative circular dichroic curve was observed for whale myoglobin and therefore indicating a right-handed helix[8]. Our results indicate that the maxima of these bands are centred at about 225 mμ, confirming previous optical rotatory dispersion data on the Cotton effect[1–3]. Approximate estimation of rotational strength yields the following values: poly-D-glutamic acid, about $+125$ in 10^{-40} C.G.S. units; poly-L-glutamic acid, about -125×10^{-40} C.G.S. units; poly-L-lysine, about -134×10^{-40} (assuming a Gaussian curve[9]). These values are in good agreement with Moffitt's theoretical prediction[4] (about 120×10^{-40}) but at variance with previously reported values for poly-L-glutamic acid[9]. The disordered form of these polypeptides (at neutral *p*H) causes the disappearance of the circular dichroic absorption band at 225 mμ, confirming the previous observations[1–3,9].

The poly-L-aspartic acid at *p*H 4·3 exhibits a negative C.D. curve centred also at 225 mμ (Fig. 2), but of smaller intensity with strength of about -35 in 10^{-40} C.G.S. units, while the poly-D-aspartic is characterized by a positive band of approximately the same absolute value of rotational strength. At neutral and alkaline *p*H, a very pronounced decrease of this C.D. curve was observed, indicating the transformation from ordered to random coil form. This behaviour is fully reversible, that is, on lowering the *p*H (from 12 to 4) the same C.D. curve reappears. The optical rotatory dispersion data of poly-L-aspartic acid at *p*H 4·2 obey the Moffitt equation and yield the b_0 value of -160, which also indicates the existence of a helical conformation, whereas at alkaline *p*H the b_0 vanishes and the dispersion follows the one-term Drude equation. The helical form of poly-aspartic acid is very sensitive to the presence of interfering substances; for example, acetate buffer 0·3 M causes a sharp decrease of the intensity of the C.D. band and a pronounced shift of the maximum from 225 mμ to 235 mμ (Fig. 2), indicating that probably another form of macromolecular conformation of poly-aspartic acid takes place. This demonstrates the advantage of circular dichroism[10] studies, which permit resolution of the optical rotatory contribution of each individual optically active transition. Work is in progress in order to gain a more complete characterization of poly-aspartic acid.

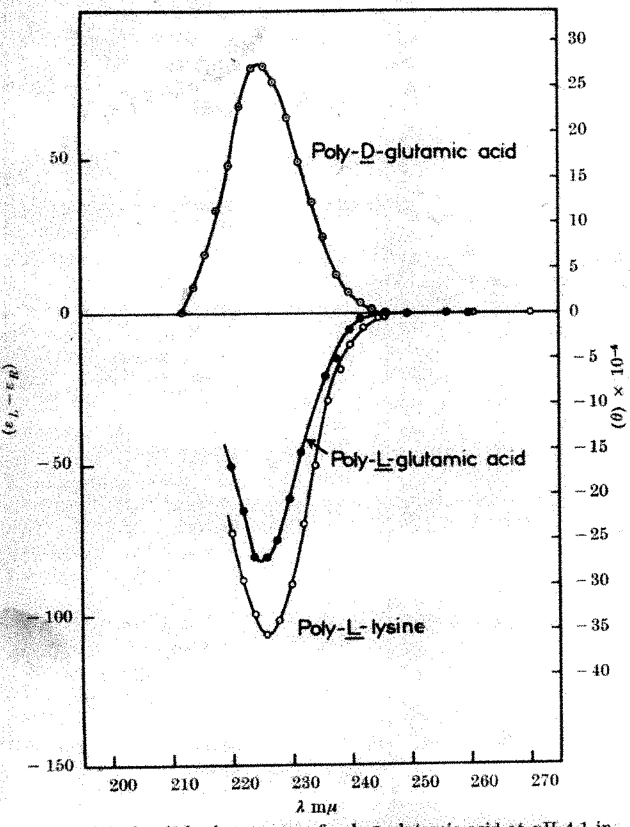

Fig. 1. Circular dichroism curves of poly-L-glutamic acid at *p*H 4·1 in 0·15 M NaCl, 0·1 acetate buffer; poly-D-glutamic acid in the same conditions; poly-L-lysine 0·2 M NaCl, *p*H 11. Measurements were carried out on a Russel–Jouan dichrograph. The apparatus is equipped with the sensitivity setting of 3, 2, 1·5 and 0·46

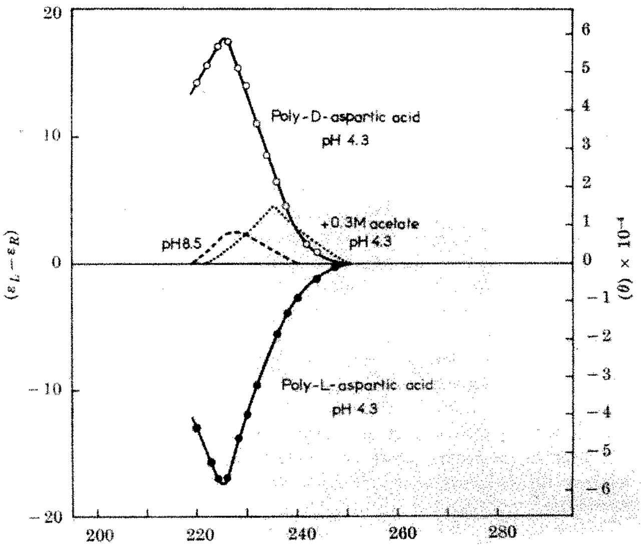

Fig. 2. Circular dichroism curves of poly-L-aspartic acid at *p*H 4·3 (–) and *p*H 8·5 (– – –) in 0·2 M NaCl

All these results indicate that poly-L-aspartic acid, like other L-polypeptides, forms a right-handed helix whereas the D-poly-amino-acid exists as a left-handed helix. Some differences observed for poly-L-aspartic-acid expressed in the relatively low rotational strength value, low value of $-b_0$, reflect less organized helical structure as compared with its homologue poly-L-glutamic acid. It appears that the rotational strength value of C.D. band at 225 mμ may be used as a measure of the amount of helical content in polypeptides.

We thank Profs. Ch. Sadron and H. Benoît for encouragement and helpful discussions. We also thank Miss H. Feigenbaum for assistance in preparation of polypeptides, and Prof. G. Ourisson and Miss H. Herman for making possible the circular dichroism measurements.

A Helical Structure in Ribonucleoprotein Bodies of *Entamoeba invadens*

THERE have been conflicting reports in the literature about the chemical nature and origin of chromatoid and related bodies found in the cytoplasm of certain protozoa[1-8] and in the spermatogenic cells of certain crustaceans[9], insects[10-11], cyclostomes[9], reptiles[12], birds[9], and mammals[13-15]. Of special importance is the recent work of Barker[1,16]. This investigator has shown in his cytochemical and electron microscope studies that chromatoid bodies in *Entamoeba invadens*, a parasite of snakes, are composed of ribonucleic acid and protein and that chromatoid bodies arise by a process of aggregation of small groups of 250–300 Å units which form polycrystalline masses in precysts and early cysts. The purposes of this report are to show: (*A*) that the chromatoid bodies are also found in axenically grown trophozoites, where there is no cyst formation, and (*B*) that the ribonucleoproteins within the chromatoid bodies are arranged in a helical pattern.

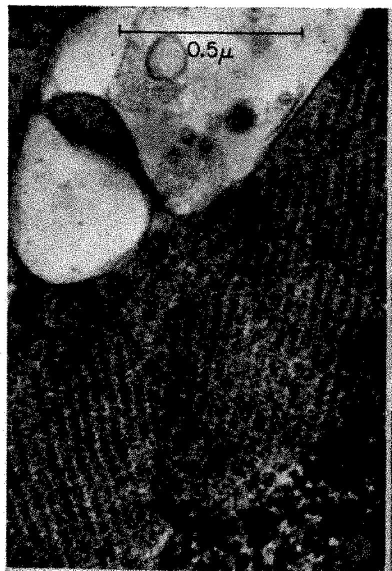
Trophozoites of the PZ strain of *E. invadens*, grown axenically in Diamond's medium[17], were fixed for 1 h at 0° C in 1 per cent OsO_4 buffered with veronal acetate at *p*H 7·4. The trophozoites were then dehydrated in ascending concentrations of ethyl alcohol with occasional gentle centrifugation and embedded in cross-linked methacrylate[18]. Polymerization was carried out at 50° C for 24 h. Thin sections, cut with glass knives in a Porter–Blum microtome, were stretched by the application of xylol, mounted on 'Formvar' and carbon-coated grids, and stained with Karnovsky's stain[19]. Electron micrographs were taken with a Philips electron microscope model Em-100 at original magnifications 9,700–13,400 and enlarged further photographically.

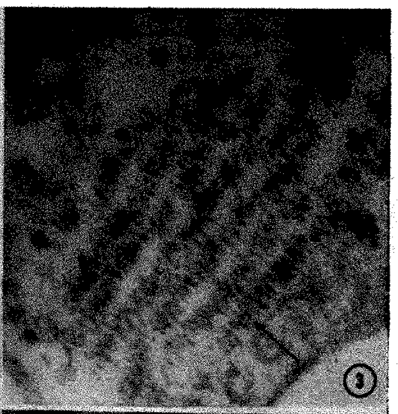
The detailed description of electron microscope studies of trophozoites of *E. invadens* will be published elsewhere; this report deals exclusively with results of studies on 'chromatoid bodies'. Two to six chromatoid bodies of varying size from 1·0 × 0·55μ to 2·9 × 0·7μ may be seen in a single trophozoite. They are scattered throughout the cytoplasm and in electron micrographs appear to be composed of bands or lamellæ arranged in parallel arrays (Figs. 1 and 2). The number of lamellæ varies from 9 to 34 depending on the size of the chromatoid body. The width of individual lamellæ ranges from 250 to 350 Å and the distance between two adjacent lamellæ is 100 to 150 Å. At higher magnification (Figs. 1, 2 and 3) the lamellæ appear to be composed of coiled fibrils which seem to form a closely packed helix. In some places the helix is particularly well defined.

This helical structure in a ribonucleoprotein body is of particular interest. Since Watson and Crick's[20] successful approach to the structure of DNA, similar procedures have been adopted by various workers to study the structure of RNA. X-ray diffraction studies of a complex of polyinosinic and polycytidylic acids gave a crystalline diffraction pattern resembling that of DNA and a non-crystalline pattern like that of RNA[21]. This suggested that RNA might have a structure like DNA[22]. Similar conclusions were also drawn from X-ray studies of soluble RNA[23] and from molecular model-building[24]. Recently, X-ray diffraction studies on crystalline yeast transfer RNA have given conclusive evidence that RNA molecules are helical in structure[22]. In another report[25], the structure of RNA has been shown to be helical in nature based on X-ray diffraction studies of ribosomes extracted from *E. coli*, *Drosophila* larvæ, rat liver and rabbit reticulocytes. Barker[16] proposed the hypothesis that the chromatoid body represents a crystalline store of ribosomes and his preliminary results of analytical centrifugation of the particles indicated that they may have sedimentation rates of approximately 180, 160 and 100*S*.

Our study shows a helical pattern in chromatoid bodies. In places the structure is clearly defined. The dimensions of the helices in the chromatoid bodies of *E. invadens* as they appear in electron micrographs are far larger than those calculated by X-ray diffraction studies for transfer ribonucleic acid[22] and for ribosomal RNA in several organisms[25]. It is too early to speculate on the interpretation of this difference, for more detailed biochemical data on the chromatoid body are needed.

The significance of the findings described in this article resides in the fact that this is the first demonstration by electron microscopy of a helical structure in ribonucleoprotein bodies. The structure disclosed seems important enough to be reflected in terminology, particularly in view of the number of different other terms used in addition to 'chromatoid bodies', most of them (including the latter) misleading and confusing. It seems appropriate, therefore,





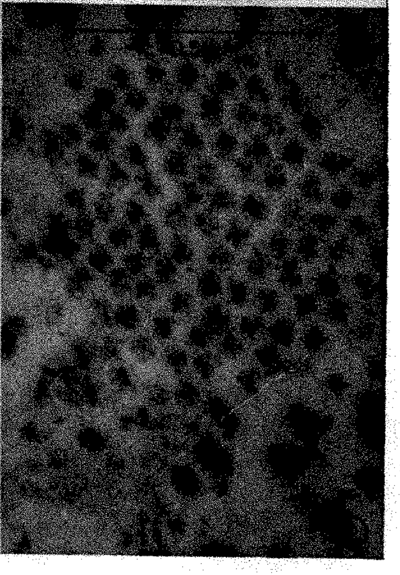


Fig. 1. Electron micrograph of 'chromatoid body' to show that in a longitudinal section it is composed of bands or lamellæ arranged in parallel arrays. The helical structure of the lamellæ can be seen at arrows

Figs. 2 and 3. Higher magnification of lamellæ. Note that the lamellæ are composed of coiled fibrils, forming a closely packed helix. The helical structure is particularly seen at arrows

Fig. 4. Cross-section through lamellæ

at this point to propose the introduction of a new, more specific term, 'helical RNP bodies', for chromatoid bodies of the same nature as those found in *E invadens* The new term combines the biochemical composition defined by Barker with the helical structure described in this article

We thank Dr William Trager for advice and Dr William Balamuth for supplying the strain of *E invadens*

Effect of DL-Ethionine on the Level of Cystathionase in Rat Liver

WE have previously reported that the level of cystathionase ('soluble' cysteine desulphurase) of rat liver is increased when L-methionine is injected in male rats maintained on a commercial diet[1] We have recently shown that a similar increase could be obtained with rats placed on a synthetic diet (diet *B*) containing 18 per cent casein, furthermore, the level of cystathionase is higher in liver of rats maintained on a synthetic diet (diet *C*) containing 60 per cent casein, and we have observed that addition of a definite quantity of DL-methionine to diet *B* increases the enzyme-level[2] These results indicate that some correlation could be established between dietary protein and the level of enzyme activity, and suggest that 'adaptation' of cystathionase is mediated, at least in part, by the content of methionine in the diet As the increase in enzyme activity found on varying methionine intakes could be the reflexion of alteration of the content of specific protein in the liver, in the investigation described here we have determined the effect of addition of DL-ethionine (*S*-ethyl/analogue of methionine) to the diets on the level of hepatic cystathionase

We used Wistar rats from the Centre de Sélection des Animaux de Laboratoire du C N R S, with mean body-weight of 80 g, the preparation of the supernatant fraction of the liver, the conditions of determination of hydrogen sulphide formation and the composition of the diets have been described earlier[2-4] The experiments were conducted as follows all rats were placed for 8 days on the diet *B*, then they were divided in two groups, the first group was maintained on diet *B*, while the second received diet *B* containing 2 5 per cent DL-ethionine After 8 days, rats were weighed and killed, the weight of liver and the activity of cystathionase were determined The contents of protein in supernatant are measured according to the method of Lowry *et al* [5]

Other experiments were similarly carried out with rats routinely maintained in diet *C* and diet *C*+2 5 per cent ethionine, furthermore, as from the results of Farber and Corban[6] ethionine inhibits hepatic protein synthesis more effectively in female than in male rats, some experiments were performed on female rats All results are expressed as μmoles hydrogen sulphide/μg protein/h

Table 1 shows the results obtained in these assays From the figures it is evident that DL-ethionine increases the level of enzyme Such an increase is rather surprising and the stimulation of cystathionase by DL-ethionine merits further comments The increase of activity was observed in male rats maintained on diets *B* and *C*, but in this last case the increase did not start before 10 days, while it is faster in rats placed on diet *B* Furthermore, we have observed no difference between male and female rats, ethionine is equally effective for the alteration of enzymatic activity Moreover, while methionine by itself is not a substrate for cystathionase, some products formed from methionine, like cystathionine, homoserine and cysteine, are good substrates, and the response of enzyme to injections of some of these substrates is an increase of level[1] If ethionine is de-ethylated, one can suppose that cystathionine and other substrates might arise; however, it seems improbable that de-ethylation of ethionine is of considerable importance in the rat[7]

Table 1 EFFECT OF ADDITION OF DL-ETHIONINE TO SYNTHETIC DIETS ON THE LEVEL OF CYSTATHIONASE

Diet		Body weight (g)	Liver weight	Mg protein/ml supernatant	H_2S μmoles/μg protein/h
I Male rats					
B	(8 days)	133	7 4	13 2	286 ± 12
B + eth	(8 days)	85	3 0	10 4	1,383 ± 95
C	(10 days)	164	6 0	14 8	795 ± 38
C + eth	(10 days)	116	3 9	12 0	840 ± 74
C + eth	(19 days)	99	4 7	12 8	1,197 ± 168
II Female rats					
C	(8 days)	130	6 3	12 9	551 ± 97
C + eth	(8 days)	84	3 1	11 7	1,143 ± 71

Natori[8] has reported that the level of methionine-activating enzyme in female rats is almost twice that of male rats, and he observed that the ethyl group of ethionine is extensively incorporated into the liver RNA fraction It might be supposed that action of ethionine may be due to the formation of an abnormal cystathionase in which methionine is partially, at least, replaced with ethionine This new protein could have different physico-chemical properties and enzymatic activity to those of normal cystathionase

An examination of the properties of purified enzyme obtained from livers of normal rats and from livers of ethionine-treated rats is under investigation

Excretion of Indolyl Acids in Phenylketonuric Monkeys

EXPERIMENTAL phenylketonuria has been induced in the rhesus monkey by feeding excess dietary phenylalanine[1,2] The phenylalanine plasma level was markedly elevated, and the urinary excretion of phenylketones and phenylacetyl glutamine were comparable with that found in children with phenylketonuria Behavioural and learning tests have demonstrated a severe degree of mental retardation in these experimental animals This report provides data on the excretion of 5-hydroxyindolyl-acetic acid and indolyl-3-acids in these monkeys and demonstrates that the role of tryptophan is similar in both the experimental disease and in phenylketonuric infants

Five normal monkeys and five experimental monkeys (*Macaca mulatta*) were studied over a one-year period Each animal was placed in a metabolic chair constructed in this laboratory and modified from that previously described[2] Only male monkeys were used and appropriate collection devices similar to those used in pediatric patients were attached to the genital area Urine samples, taken over 24-h periods, were collected in a bottle kept in ice Several crystals of thymol were added to each bottle as a preservative The urine was kept frozen at – 10° C until ready for analysis The animals received commercially modified milk either with or without added phenylalanine (3 0 g/kg/body-weight/day) and were fed *ad lib* at 4-h intervals The method of Udenfriend *et al* [3] was used for the determination of free 5-hydroxyindolylacetic acid (5-HIAA), and the method of Weissbach *et al* [4] for free indolyl-3-acids (indolyl-3-acetic, indolyl-3-lactic and indolyl-3-pyruvic acids) The control animals ranged in age from 3 to 18 months, whereas the experimental animals varied from 8 months to 24 months at the time of the urine collections

The analysis of the 24-h urine collections is shown in Table 1 The excretion of indolyl-3-acids was not significantly different between the experimental and the control groups, but the decreased excretion of 5-HIAA in the experimental group was highly significant ($P < 0\ 0025$) Although not shown in Table 1 (for reasons of brevity), no differences in base line values were found for either the indolyl-3-acids or for the 5-HIAA between the younger and older animals In addition there was no evident correlation between the total 24-h excretion of the indolyl acids and the weight of the monkey or the length of time on phenylalanine diet.

Table 1 EXCRETION OF 5-HYDROXYINDOLYL-ACETIC ACID AND INDOLYL-3-ACIDS IN NORMAL AND PHENYLKETONURIC MONKEYS PER 24 H

Group	No of animals	No of urine collections	5-HIAA (μg/day)	3-Indolyl-acids † (mg/day)
Control	5	15	304 ± 230*	1 48 ± 2 03*
Experimental	5	10	47 ± 26*	1 15 ± 1 45*

* Standard deviations are reported for differences between collections
†Total of indolyl-3-acetic, indolyl-3-lactic and indolyl-3-pyruvic

The close biochemical relationship between phenylalanine and tryptophan and tryptophan metabolites has found support in a number of observations Work in this laboratory has shown that excess phenylalanine causes an *in vitro* inhibition of tryptophan hydroxylation in rat liver[5] It was, therefore, not surprising that decreased serotonin was found in the brain and liver of rats fed excess phenylalanine[6] Since 5-HIAA is the end excretory product resulting from oxidation of serotonin, any decrease in excretion represents either an inability to form the serotonin precursor (5-hydroxytryptophan) from hydroxylation of tryptophan or an inability to decarboxylate this product Another factor which influences 5-HIAA excretion is the amount of tryptophan absorbed from the intestinal tract before it enters the blood Akedo and Christensen[7] have reported evidence of competition between certain amino-acids in their transfer across the intestine, and it is not unlikely that excess phenylalanine may likewise interfere with the intestinal absorption of tryptophan McKean *et al* [8], and Guroff and Udenfriend[9] have shown that excess phenylalanine and certain other amino-acids also inhibit transport of 5-hydroxytryptophan across the blood-brain-barrier and thus effectively decrease the formation of serotonin

An increased indolyl-3-acid excretion by human phenylketonurics has been reported by Armstrong and Robinson[10] This increase was attributed primarily to indolyl-3-lactic acid, which is not distinguished from indolyl-3-acetic acid in the methods described here The site of formation of the 5-HIAA is probably different from that at which indolyl-3-acids are formed

Following a tryptophan load test, Toda and Bessman[11] found an increased excretion of indican and indolyl-3-acetic acid and a decreased excretion of kynurenic acid, xanthurenic acid and *N*-methylnicotinamide These findings are understandable, since the former compounds arise largely from intestinal putrefaction of unabsorbed tryptophan whereas the latter products arise mainly from tissue metabolism of absorbed tryptophan These observations would seem to offer further evidence for decreased absorption of tryptophan followed by absorption of its putrefactive products from the lower intestine[4] Since a milk diet modifies the intestinal microflora, the effect of an excess phenylalanine milk diet on excretion of indolyl-3-acids was probably an added factor in our experimental monkeys The effect of diet on intestinal flora could also be why all phenylketonuric children do not excrete increased amounts of indolyl-3-acids Bessman and Toda[12], on the basis of indole tolerance tests, suggest that the increased excretion of indican and indolyl-3-acids in phenylketonuric children is due to a more general derangement of indole metabolism However, another explanation may be that these compounds are increased mainly as a result of decreased tryptophan absorption whereas the decreased excretion of 5-HIAA is due to alterations in the activity of the hydroxylases and decarboxylases as well as to effects on the transport of amino-acids

The decreased 5-HIAA excretion found in phenylketonuric monkeys demonstrates still another biochemical similarity of the experimental condition to that found in the human disease[13] The return to normal of the excretion of 5-HIAA by phenylketonuric patients treated with a diet low in phenylalanine[14] is comparable with removal of the phenylalanine excess diet in the monkey

Partial Separation of Rat Liver Mitochondrial Amine Oxidases

ALTHOUGH the mitochondrial monoamine oxidase (monoamine O_2-oxidoreductase (deaminating), *EC* 1 4 3 4) is generally believed to possess broad substrate specificity[1], numerous results may be considered as indirect evidence of 'multiplicity' of mitochondrial amino oxidases[2–7] Nevertheless, separation of mitochondrial amine oxidases has not so far been reported to my knowledge

This communication describes an example of partial separation of rat liver mitochondrial amine oxidases attacking two different amines suitable for spectrophotometric determination of the enzymatic activity, namely, *m*-nitro-*p*-hydroxybenzylamine (PHB) (ref 8) and *p*-nitrophenylethylamine (PN) (ref 9).

Both substrates were synthesized by Dr N A Kitrossky and G A Leontyeva (Department of Organic Chemistry, Institute of Biological and Medical Chemistry) Mitochondria prepared from rat liver homogenates[10] were treated by hypotonic phosphate[11], solubilized in the presence of a non-ionic detergent '*OP*-10' (final concentration 1 25 per cent) as described earlier[12] and adjusted to *p*H 7 00 All the subsequent operations were performed at 3° The solubilized material was applied to a 24 mm × 95 mm 'Brushite' column[13,14] Stepwise elution by 0 1, 0 4, 0 5 and 0 7 M potassium-phosphate buffers, *p*H 7 00, containing 1 25 per cent (w/v) of '*OP*-10', was carried out 15-ml fractions of effluent were collected at a flow rate of 4 ml /min Protein content was determined by the method of Lowry *et al* [15] with precautions necessary when working in presence of phosphates and detergents[16] PHB oxidation was followed by measuring optical density increase (due to formation of *m*-nitro-*p*-hydroxybenzaldehyde) at 315 mμ in 10-mm cuvettes put in a thermostat at 37° (spectrophotometer *SF*–4) for 5 min The samples containing 0 2 M potassium-phosphate buffer (0 5 ml), enzyme solutions (0 2–2 0 ml), PHB (final concentration 5 3 × 10^{-4} M) were brought up to 3 0 ml with water The spectrophotometric unit (SU) was defined as a quantity of enzyme necessary to cause an increase in optical density by 0 001 in 1 min For PN oxidation assay PHB in samples described was substituted by PN (1 mg per sample) and after incubation at 37° during 2 h optical density measurements at 453 mμ in 10-mm cuvettes of 'FEKN–57' photoelectric colorimeter were taken The assay yields fairly reproducible results and proved to be very sensitive The quantity of the enzyme necessary to cause the optical density increase by 0 01 in the standard conditions was defined as a unit (un) of enzymatic activity

Table 1 PARTIAL SEPARATION OF RAT LIVER MITOCHONDRIAL AMINE OXIDASES

	Starting material	Combined effluent fractions				Recovery (%)
		1–8	9–16	17–25	26–34

Un /mg of protein (max)	30 0	4 4	325 0	400 0	285 0	

Results of one of five similar experiments presented in Table 1 indicate that 0 4 M phosphate elutes up to 56 per cent of the 'PN-deaminating' enzyme applied to the column while no 'PHB-deaminating' activity could be detected in these fractions At higher phosphate concentrations both enzymatic activities are found in eluates While up to 90 per cent of initial 'PN-deaminating' activity are recovered in eluates, the recovery of 'PHB-activity' was rather low Our preliminary observations suggest the phenomenon is caused by increased lability of the later enzyme on column chromatography

Further work on separation and purification of mitochondrial amine oxidases, designated at present by a common term 'monoamine oxidase', as well as investigation of their substrate specificity and effect of inhibitors are in progress and will be published elsewhere in Russian

A Pentose identified in the Carbohydrate Group of Spongin

Bergmann and Feeney[1] have isolated a new thymine pentoside from a sponge (*Cryptotethia*) Isolation and identification of the carbohydrate fragment of this nucleoside have been unsuccessful, but the high dextrorotatory power of this nucleoside suggests that it is a xylofuranoside rather than the as yet unknown thymine nucleoside

Previously we had examined[2] the carbohydrate group of a scleroprotein (spongin) and identified the sugar (galactose) by paper chromatography In the work recorded here we have identified a different sugar (xylose) in the carbohydrate group from *Euspongia officinalis*

Euspongia officinalis were cut in very small pieces, mixed with 2 N hydrochloric acid and shaken in a vacuum several times to remove the calcium carbonate The material so obtained was washed with distilled water and dried in a vacuum desiccator over phosphorus pentoxide To 1 5 g dried sponge were added 150 ml water and this mixture heated for 6 h at 80° C under a reflux condenser on a water-bath, and filtered The filtrate was concentrated to 1–2 ml on the water-bath under vacuum (sample I) The same procedure was repeated using hydrolysis with

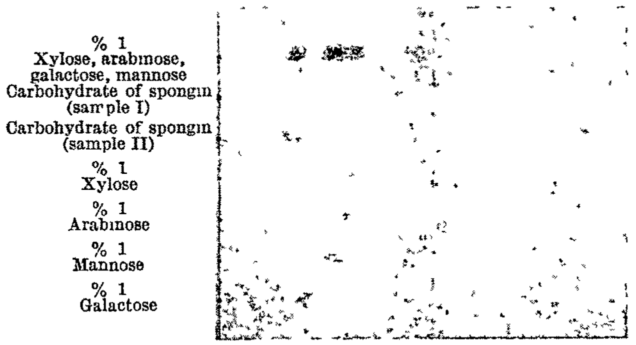

Fig 1

0 1 N sulphuric acid at 62° C, the acid neutralized with barium carbonate and the mixture filtered and concentrated (sample II) Both samples gave a positive Molisch reaction and there was no reducing action with aniline hydrogen phthalate reagent[3]

Samples I and II were further hydrolysed separately for 5 h with an equal volume of 2 N sulphuric acid and neutralized with barium carbonate, filtered and concentrated to 1–2 ml The hydrolysates were run for 30 h on paper chromatograms (Whatman No 1 paper descending technique) using the organic layer from a freshly prepared *n*-butanol–acetic acid–water mixture (4 1 5 v/v/v) (ref 4) The chromatograms were sprayed with aniline hydrogen phthalate reagent and then dried in an oven at 110° C The chromatograms showed a pale spot corresponding to authentic xylose (Fig 1)—a sugar more generally obtained from plants

Homarine (*N*-Methyl Picolinic Acid) in Muscles of some Australian Crustacea

During the examination of guanidino compounds in trichloroacetic acid extracts of crustacean muscles, it was observed that treatment of paper chromatograms with alkaline α-naphthol diacetyl[1] sometimes resulted in the appearances of a yellow spot in addition to the pink spots characteristic of guanidine and its mono- and di-*N*-substituted derivatives The unknown compound responsible for this yellow spot was present in muscle extracts from the marine crustacea, Moreton Bay lobster (*Thenus orientalis*), king prawn (*Penaeus plebejus*), tiger prawn (*Penaeus esculentus*), and spiny crayfish (*Jasus verreauxi*), but was absent from the corresponding extracts from the fresh-water organisms, Murray River crayfish (*Euastacus elongatus*) and fresh-water crayfish (*Cherax albidus*) This variation in distribution prompted further investigations, and this communication reports evidence for the identification of the compound as homarine[2]

Preliminary experiments with paper chromatograms of crude extracts indicated that the compound strongly absorbed ultra-violet light in the region of 270 mμ and that the formation of yellow colour was due to the alkali and α-naphthol contained in the Barritt reagent[1] Isolation of the compound was achieved by the following method 10 kg of freshly excised prawn muscle (from either *P plebejus*, or *P esculentus*) was homogenized with 10 l of methanol in a Waring blender and the mixture allowed to stand, with occasional stirring, for several days at room temperature The mixture was then filtered, the residue was re-extracted with 10 l of methanol and the methanolic extracts were combined and concentrated to approximately 500 ml by vacuum distillation. The copious precipitate which formed during this distillation was removed and discarded The remaining solution was passed several times through columns of 'Dowex-1' (OH⁻ form; 500 g) and 'Dowex-50' (H+ form, 500 g) ion-exchange resins Progress of the compound was followed by ultra-violet absorption (273 mμ) and paper chromatography of eluate samples The compound passed unretarded through the anion exchanger, but was retarded on the cation exchanger and appeared in the eluate only after the passage of three bed-volumes of distilled water This retardation was in contrast to suggestions that homarine is firmly bound to strong cation-exchangers[3,4] Eluates containing the compound were pooled and concentrated to a viscous oil by vacuum distillation This oil was dried *in vacuo* over phosphorus pentoxide and recrystallized twice from absolute ethanol to yield 4 g of white hygroscopic crystals A sample of these crystals was further purified by chromatography on a cellulose column using *n*-butanol, saturated with water, as the mobile phase Paper-chromatographic examination of the recrystallized product, using five different solvent systems, revealed only one ultra-violet-absorbing spot in each case No ninhydrin-reacting materials were detected on these chromatograms

Comparison of the ultra-violet spectrum of the product with published spectra[5] led to tentative identification as homarine This was confirmed by comparisons of other properties of the isolated compound with those of homarine synthesized by oxidation of α-picoline to α-picolinic acid and methylation of the latter by dimethylsulphate[6,7] (Table 1) The isolated and synthetic compounds also showed identical behaviours on ion-exchange resins and gave the same R_F values after ascending paper chromatography in several solvent systems Thus, R_F values at 25° C (Whatman No 1 paper) were 0 30 in *n*-butanol glacial acetic acid water (73 10 17) and 0 75 in *tert* -butanol ammonia water (60 30 10)

Table 1 COMPARISONS OF ISOLATED COMPOUND WITH HOMARINE

Compound	Ultra-violet spectra			
	λ_{max}, *p*H 7	λ_{min}, *p*H 7	λ_{max}, *p*H 1	ε at λ_{max}, *p*H 7
Isolated compound	274 mμ	241 mμ	271 mμ	6,200
Homarine, refs 4 and 5	273 5 mμ	240 mμ	270 mμ	6,325

Compound	Elementary analysis (%)*		
	C	H	N
Picrate of isolated compound (m p 153°–154° C)	42 7	2 8	15 1
Synthetic homarine picrate (m p 155°–156° C)	42 6	2 8	15 3

* Values for synthetic homarine picrate calculated for $C_{13}H_{10}O_9N_4$

Synthetic homarine, when spotted on filter paper and sprayed with alkaline α-naphthol (equal volumes of 5 N sodium hydroxide and 1 per cent α-naphthol in ethanol), also gave the yellow colour A number of other related compounds were tested with this reagent and yellow colours were obtained with *N*-methyl pyridinium iodide, pyridine betaine, α-picoline methiodide, and trigonelline (*N*-methyl nicotinic acid) Negative results were obtained with pyridine, pyridine *N*-oxide, nicotinic acid, picolinic acid, pyridoxine hydrochloride, betaine hydrochloride, and choline chloride From these limited investigations it appears that a pyridinium ring system, containing an alkyl or substituted alkyl radical as the *N*-substituent, is required for this colour reaction

Solvent Systems for Silica-gel Column Chromatography of Indole Derivatives

An earlier paper[1] described a method for separating a number of indole derivatives and auxin-like substances in plant extracts, using silica-gel partition columns and petroleum ether: *n*-butyl alcohol solvents used with a step-wise elution technique. Further investigations, the results of which are reported here, have extended this technique to include a number of other useful solvent mixtures.

Most eluting mixtures consisted of a more polar solvent that had been saturated with 0·5 M formic acid, and a non-polar one. A few consisted only of the acid-saturated polar constituent. The column, described in detail elsewhere[1], was prepared by hydrating 8·0 g of silica gel with 5·0 ml. of 0·5 M formic acid, then slurring the hydrated silica gel with the eluting solvent and pouring into a glass tube 14 mm internal diameter. The column was about 13 cm high after it was packed by applying air pressure from a hand squeeze bulb. Approximately 5×10^{-7} moles of each indole derivative were chromatographed and collected in 3-ml. fractions on a fraction collector. When mixtures of indoles were chromatographed it was often necessary to use a step-wise elution technique in which increasing concentrations of the more polar constituent were utilized in order to obtain a satisfactory separation. Each fraction was taken to dryness in the test tube in which it was collected *in vacuo* by use of a rotating evaporator (Rotary Evapo-Mix, manufactured by Buchler Instruments, Inc., Fort Lee, New Jersey). The indoles were afterwards detected with the Gordon–Weber modification of the Salkowski reagent[2].

Most of the solvent mixtures used *n*-hexane as the non-polar phase. Hexane does not cause column cracking at elevated laboratory temperatures as does the petroleum ether, b.p. 30°–60°, used in earlier work[1]. The hexane solvent mixtures are listed in Table 1, and their chromatographic properties with seven indoles of widely varying solubility characteristics in Table 2. As a group the alcohol-hexane mixtures were the most versatile. At a given concentration they could elute a particular indole more readily than any of the other solvents. With one or two exceptions they were able to separate the seven indoles listed in Table 2. A definite inferiority of one alcohol over another one was not established, with the exception of hexyl alcohol, and possibly *n*-butyl alcohol, where their higher boiling points may be objectionable. The ester-hexane mixtures were intermediate in their ability to elute the indoles. They generally effected elution and separation of all the indoles except tryptophan and tryptamine. All but two of these esters have boiling points appreciably lower than the alcohols. This is a distinct advantage in laboratories not equipped for efficient evaporation of liquids from test tubes. Butanone-hexane was a slightly stronger eluting solvent than the esters; it could elute tryptophan and tryptamine. Chlorinated hydrocarbon-hexane mixtures were least satisfactory as a group. Methylene chloride, chloroform, and 1,2-dichloroethane in high concentrations were able to elute all the indoles of Table 2 except tryptophan and tryptamine. Carbon tetrachloride and trichloroethylene were able to efficiently elute only ethyl indoleacetate and indoleacetonitrile, and would thus appear to have little value as eluting solvents for silica-gel column chromatography of indole compounds. In no case did any of the chlorinated hydrocarbons resolve ethyl indoleacetate and indoleacetonitrile.

Table 1. Some Solvents used for the Silica-gel Column Chromatography of Indole Derivatives

n-Hexane : methylene chloride
n-Hexane : chloroform
n-Hexane : carbon tetrachloride
n-Hexane : 1,2-dichloroethane
n-Hexane : trichloroethylene

n-Hexane : 2-butanone

n-Hexane : methyl formate
n-Hexane : ethyl formate
n-Hexane : methyl acetate
n-Hexane : ethyl acetate
n-Hexane : *n*-propyl acetate
n-Hexane : methyl propionate
n-Hexane : ethyl propionate

n-Hexane : *n*-butyl alcohol
n-Hexane : *sec*-butyl alcohol
n-Hexane : isobutyl alcohol
n-Hexane : *t*-amyl alcohol
n-Hexane : *n*-hexyl alcohol

Table 2. Ability of Chromatography Solvents to elute Indole Derivatives from Silica Gel Columns

	Concentration of solvent in *n*-hexane required for elution		
	Chlorinated hydrocarbons	Esters and 2-butanone	Alcohols
Ethyl indole-3-acetate	50–100%	3–5%	0·5–1%
Indole-3-acetonitrile	50–100%	3–5%	0·5–1%
Indole-3-butyric acid	100% to not eluted	25%	5–10%
Indole-3-acetic acid	100% to not eluted	25%	5–10%
Indole-3-acetamide	100% to not eluted	50%	25–50%
Tryptophan	not eluted	100% to not eluted	100%
Tryptamine	not eluted	100% to not eluted	100%

Using the solvent systems above, the indoles were generally eluted by 50 ml. or less of solvent and came off the column as sharp peaks in volumes of about 6–15 ml. Substances said to be not eluted did not come off the column when quantities of 100–200 ml. of the solvents were used.

The choice of the non-polar constituent does, of course, markedly affect the elution pattern. Benzene with *n*-butyl alcohol, for example, eluted ethyl indoleacetate and indoleacetonitrile much more readily than did *n*-hexane. Even closely related non-polar solvents could give different results; *n*-pentane and petroleum ether (b.p. 30°–60°) with 0·2 per cent *n*-butyl alcohol were able to effect separation of ethyl indoleacetate and indoleacetonitrile, whereas *n*-hexane in similar or any other likely concentration was unable to do so.

With one or two exceptions all the solvent systems eluted the seven indoles in the same order, if indeed they eluted and separated them at all. That order was ethyl indoleacetate, indoleacetonitrile, indolebutyric acid, indoleacetic acid, indoleacetamide, tryptophan, and tryptamine.

Full details of the solvent systems used have been purposely omitted since the substances to be dealt with in a particular problem are not likely to be exactly those used here. The information given should be sufficient, however, to guide the investigator towards a wise choice for his own circumstances.

This work was carried out while the author was a member of the staff of the Department of Pomology, New York State Agricultural Experiment Station, Cornell University, Geneva.

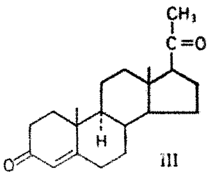
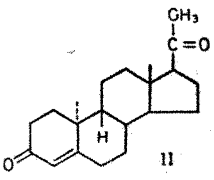
Metabolism of some Progestationally Active 9β,10α-Steroids in Man

In 1960 Reerink *et al.*[1] announced a new class of hormonally active steroids named 'retro-steroids'. This class is characterized by the β-position of the C-9-hydrogen atom and the α-position of the C-10-methyl group.

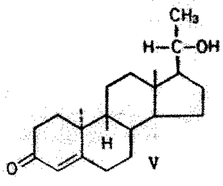
In clinical trials two members of this class, 6-dehydro-9β,10α-progesterone (generic name, 'Dydrogesterone') (I) and 9β,10α-progesterone (II), were found to exert a markedly progestational activity when administered



III



II



V

orally[2,3]. This suggested the possibility that their intermediate metabolisms would be different from that of progesterone (III). Therefore these two compounds were labelled with tritium (at carbon atom 4) (ref. 4), in order to examine their urinary metabolites.

In four experiments each of the two labelled compounds, containing 30–60 μc. of tritium (specific activities 0·1 and 0·5 μc./mg), were administered orally to two post-menopausal women, and urine was collected for 6–12 days. After extraction with ether, the urines were hydrolysed exhaustively with β-glucuronidase ('Ketodase', Warner–Chilcott Company) and extracted with toluene (first toluene extracts). The unhydrolysed radioactive material remaining in the urines was then extracted with tetrahydrofuran and hydrolysed according to Jacobsohn and Lieberman[5]. The radioactive substances liberated were extracted with toluene (second toluene extracts).

Virtually no radioactivity was found in the ether extracts and in the spent urines. Approximately half the total urinary radioactivity was present in the first toluene extracts. Thin-layer and column chromatography of these extracts revealed that in each case approximately 90 per cent of the radioactivity could be attributed to a single compound. In the case of I this proved to be 20α-hydroxy-9β,10α-pregna-4,6-dien-3-one (IV), while in the case of II it was 20α-hydroxy-9β,10α-pregn-4-en-3-one (V).

Urinary IV was obtained in a crystalline form with the same molar radioactivity as the administered I. Its identity with authentic IV is based on its chromatographic properties and ultra-violet and infra-red absorption spectra, as well as on the determination of melting point (174°–176° C) and mixed melting point.

Urinary V was identified with authentic V on the basis of its chromatographic properties, ultra-violet and infra-red absorption spectra, and co-crystallization—to constant specific radioactivity—of the radioactive compound and the added inactive compound. Also in this case the molar radioactivity was the same as that of the administered II.

The second toluene extracts, which were obtained following perchloric acid hydrolysis, were found to be less homogeneous than the first toluene extracts. Paper chromatography indicated in each case the presence of at least ten radioactive substances. Both IV and V were found, although in smaller quantities than in the first toluene extracts; also their 20β-hydroxy-isomers were detected. In the paper chromatography systems used all the other radioactive substances had a more polar behaviour than IV and V. Work on their identification is in progress.

We are not aware of the occurrence of 20α-hydroxy-pregn-4-en-3-one in human urine after administration of progesterone. Since the principal urinary metabolites of the retro-steroids investigated are the 20α-hydroxylated forms, it seems justifiable to postulate a major difference in the metabolism of progesterone and of 9β,10α-progesterone.

We thank Dr. H. van Kamp of N. V. Philips–Duphar Laboratories for putting the authentic compounds IV and V at our disposal.

PHYSIOLOGY

Changes of Dehydrogenase Activity during Transneuronal Atrophy

ALTHOUGH the cytology of transneuronal atrophy in the lateral geniculate nucleus is well documented in cat[1], cytochemical studies of transneuronal atrophy are lacking. In the cat there are 3 laminæ in each nucleus. Following unilateral enucleation, the neurones of the middle lamina of the ipsilateral lateral geniculate nucleus and the first and third lamina of the contralateral lateral geniculate nucleus undergo transneuronal atrophy. The opportunity of observing normal and atrophied laminæ side by side permits an immediate appreciation of any cytochemical changes in the atrophied lamina with respect to the adjacent normal control lamina.

Twenty 10-week-old kittens underwent unilateral enucleation, and 2 months later the animals were killed and the lateral geniculate nucleus from each side removed and sectioned at 25μ thickness. Some sections were incubated with the appropriate substrate and the tetrazolium salt nitro-BT according to the technique of Nachlas *et al.*

The following enzymes were investigated: TPN-diaphorase, DPN-diaphorase, the dehydrogenase of 6-phosphogluconate, succinate, lactate-DPN and α-glycerophosphate. The remaining sections were stained with cresyl violet for routine cytology.

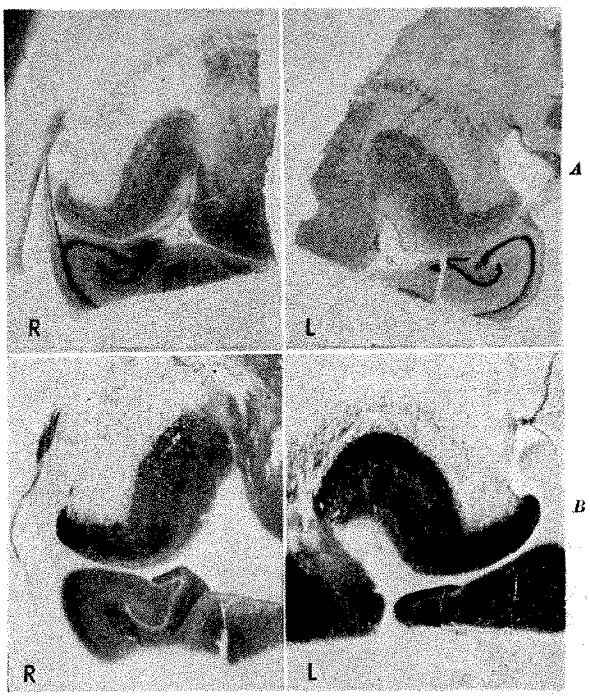

Fig. 1*A*, Parasagittal section of the right (*R*) and left (*L*) lateral geniculate nuclei following enucleation of the left eye. Cresyl violet. Noteworthy is the appearance of normal and atrophied laminæ side by side. *B*, Section adjacent to that shown in Fig. 1*A*. The substrate is succinate. Noteworthy is absence of succinic dehydrogenase activity in the atrophied laminæ

Fig. 1*A* demonstrates the transneuronal atrophy in the right and left lateral geniculate nuclei following enucleation of the left eye. Fig. 1*B* illustrates the marked decrease in succinic dehydrogenase in the atrophied laminæ as compared with the normal adjacent laminæ. A decrease in enzyme activity was characteristic for all substrates except α-glycerophosphate, with which there was no difference in enzyme activity between normal and atrophied laminæ.

Although these observations are of interest in themselves, their primary importance lies in illustrating an approach to the examination of the cytochemical correlates of transneuronal atrophy which has the advantage of permitting simultaneous observation of control (normal) and experimental (atrophied) neurones side by side.

Glycogenolysis in Aliquots of Glycogen Bodies of the Chick

PREVIOUS attempts to change the glycogen concentration in the glycogen body of birds failed[1-4] except for a few cases in which it was slightly increased[5,6]. In the experiments recorded here the effect of tissue homogenates on the polysaccharide of the glycogen body of the chick was examined. Glycogen bodies of chicks 1–4 weeks old were isolated, weighed on a Roller Smith torsion balance and homogenized in glass tissue-grinders. Ringer's solution, or isotonic sodium chloride buffered with 0.01 M phosphate to *p*H 7.4, was added to the homogenate in the proportion of 1 ml. per mg of tissue. Twenty-four aliquots of 1 ml. were then prepared from the homogenate and were divided into 4 groups of 6 each. Ringer's solution (0.2 ml.) was added to the aliquots of one group and 0.2 ml. of tissue homogenate (containing 20 mg of chick skeletal muscle, liver or brain) to the others. To the samples of the first group, in 2 series of experiments ATP, DPN+ and glucose-6-phosphate (1 mg each) were added. Two aliquots of each group were extracted[7] for glycogen immediately, two after 4 h and 2 after 24 h of incubation at room temperature (70° F.). Glycogen was assayed colorimetrically by the anthrone method[8].

In the first group of aliquots, containing only homogenate of glycogen body, 25 per cent of the polysaccharide was destroyed in the 24-h incubation (Table 1). Addition of ATP, DPN and glucose-6-phosphate (first and second series) had no effect. In the 3 other groups, to which homogenates of other tissues were added, the breakdown of glycogen was greater. In the presence of skeletal muscle homogenate more than 75 per cent of the initial glycogen was destroyed during the 24-h incubation. Brain homogenate was the least glycogenolytic of the 3 homogenates studied.

An analysis of variance of the data of Table 1 reveals that the time differences in each group and the differences between the 4 groups are statistically significant.

The results obtained indicate that hydrolysis of the glycogen body polysaccharide is increased by homogenates of other tissues (muscle, liver and brain), suggesting that it is of the same nature as that in these tissues. Bloom *et al.*[9] and Russell and Bloom[10] distinguish in liver and muscle a trichloroacetic acid (TCA) soluble fraction of glycogen (free glycogen) and a TCA insoluble fraction (bound glycogen). In the glycogen body all the glycogen is extractable with cold trichloroacetic acid[4]. This, however, does not mean that the polysaccharide in the glycogen body is different from that of liver and skeletal muscle. According to Hanson, Schwartz and Barker[11] the amount of the so-called bound glycogen (the TCA insoluble fraction) depends on the amount of protein precipitated. The glycogen body is extremely poor in tissue protein; the precipitate in a TCA extract and the amount of bound glycogen would be, consequently, negligible.

The relatively low rate of glycogen hydrolysis in aliquots of glycogen body alone could not be attributed to the lack of phosphorus, the addition of ATP, DPN and glucose-6-phosphate was without any effect. Similarly, the presence of an inhibitor would appear to be ruled out, since then muscle or liver homogenate would be expected to have no effect. The results suggest that the glycogen body is relatively poor in glycogenolytic enzymes. In favour of this hypothesis is also the fact that the cells in the glycogen body, almost entirely filled with glycogen, are poor in cytoplasm and contain only a few mitochondria[12]. This, perhaps, explains the low glycogenolytic activity in the glycogen body.

Inhibitory Effects of Œstrogens on Augmented Activity of Endometrial Carbonic Anhydrase caused by 4,4′-Methylenedianiline

PREVIOUS work[1] has shown that 4,4′-methylenedianiline causes an increase in the endometrial carbonic anhydrase when administered to rabbits. The mechanism under-

* Mean ± *S E*

† Percentage inhibition is expressed as $\frac{Rm - Re}{Rm - C} \times 100$, Rm = uterine enzyme response to methylenedianiline alone, Re = uterine enzyme response to combination of methylenedianiline and œstrogen, C = control level

lying the activating effect of methylenedianiline on the endometrial enzyme is considered to be dependent on the adrenals, presumably due to the release of progestogen arising by a block of adrenal corticosteroidogenesis Since evidence[2–4] concerning antagonisms between œstrogen and progesterone on endometrial carbonic anhydrase has been given, attempts were made to clarify how certain œstrogens affect the response of endometrial carbonic anhydrase to methylenedianiline

A modified Clauberg test[5] was used Immature albino rabbits, approximately 1 5 kg in weight, were primed with 5 μg of œstradiol once daily for seven days The animals were then subjected to treatment for 4 days with methylenedianiline and œstrogen The standard total dose of methylenedianiline was 500 mg and œstrogen was used in logarithmic spaced doses of 0 002–0 2 mg

The rabbits were then killed by breaking their necks 24 h after the last injection The uteri were removed and rinsed with cold saline The endometrium was dissected, weighed rapidly on a torsion balance and homogenized with distilled water for carbonic anhydrase analysis The carbonic anhydrase content of homogenate was then estimated by the method of Miyake and Pincus[6], the activity being expressed in terms of enzyme units/g wet weight of the endometrium[3]

The results are shown in Table 1 When a total of 500 mg of methylenedianiline was given systemically, an increase in the content of endometrial carbonic anhydrase was invariably noted However, following treatment with a combination of methylenedianiline and each œstrogen, a typical fall in the enzyme activity was observed, the extent of which depended on the dosage of œstrogen In a dose of 0 2 mg, the full effect of methylenedianiline was completely nullified by œstradiol, ethynyl œstradiol and hexœstrol However, some difference in degree of inhibition exists among each œstrogen Degree of response was directly related to the log dose of œstrogen in a nearly straight line

The results recorded here suggest that the œstrogens used are effective in inhibiting the methylenedianiline-induced endometrial carbonic anhydrase increase In previous work, treatment with cortisone effected a substantial inhibition of the endometrial carbonic anhydrase response to methylenedianiline It was suggested that the response was due to the suppression of production of ACTH by cortisone In numerous observations[7–9], the ability of œstrogen to cause hypertrophy of the adrenal cortex which is attributed to a release of ACTH in rats has been emphasized A different view was proved by Vogt's demonstration[7] showing that in the rabbit neither the adrenal histological structure nor the corticoid secretion was altered by the treatment, probably due to species difference in the response of adrenal histology to œstrogen Also, it has already been shown[4] that œstrogens themselves do not affect the activity of endometrial carbonic anhydrase In the investigation reported here it is thus possible that œstrogen-progestogen antagonism in the uterus is responsible for the ineffectiveness of methylenedianiline

HÆMATOLOGY

The Xg Blood Groups of Negroes

SAMPLES of blood from 219 unrelated Negroes, mostly from New York or Jamaica, have been tested for the X-linked blood group antigen Xg^a The antigen is significantly less frequent in these Negroes than it is in Caucasians as the following comparison shows

	Male Xg(a+)	Female Xg(a−)	Male Xg(a+)	Female Xg(a−)
Negro	65	54	80	20
Caucasian	516	280	674	80
	χ^2 for 1 d f = 4 7		χ^2 for 1 d f = 7 5	

The number of Negroes is small because tests have mainly been confined to members of diagnostic panels and to parents of families in linkage studies The 1,550 Caucasian samples were mostly from British people, this number includes 1,008 samples previously reported[1]

Gene frequencies calculated from the figures for males and females are

	Xg^a	*Xg*
Negroes	0 550	0 450
Caucasians	0 661	0 339

Phenotype frequencies calculated from these gene frequencies are very close to those observed (Table 1)

Table 1 XG PHENOTYPE FREQUENCIES IN NEGROES AND CAUCASIANS

	Negroes				Caucasians			
	Males		Females		Males		Females	
	Exp	Obs	Exp	Obs	Exp	Obs	Exp	Obs.
Xg(a+)	0 550	0 546	0 797	0 800	0 661	0 648	0 885	0 894
Xg(a−)	0 450	0 454	0 203	0 200	0 339	0 352	0 115	0 106

We thank Dr A Cahan, of Knickerbocker Biologics, New York, and Dr J D Mann, of the Butterworth Hospital, Grand Rapids, for generous gifts of the precious anti-Xg^a The samples of cells from Negroes were sent mostly by Dr Cahan, Dr I Dunsford, Sheffield, Dr V A.

IMMUNOLOGY

Protective Effect of Killed Trypanosome Vaccines with Incorporated Adjuvants

Attempts to control protozoal diseases by active immunization were unsuccessful until Mulligan *et al.*[1] showed that chickens could be partially protected against sporozoite-induced *Plasmodium gallinaceum* infection by means of an inactivated sporozoite preparation. Freund *et al.*[2,3] later immunized ducks against *P. lophurae* by incorporating the antigen in the aqueous phase of a water-in-oil emulsion containing killed mycobacteria.

We have been examining the adjuvant effect of a large number of miscellaneous substances on diphtheria toxoid and of some of these on *Trypanosoma congolense* antigen. A selected group of the adjuvants most effective with *T. congolense* antigen have also been tested with *T. cruzi* antigen.

The antigen was prepared by separating trypanosomes from the blood of heavily infected mice. Mouse red blood cells were agglutinated by the addition of mouse erythrocyte antiserum or phytohæmagglutinin. The trypanosomes trapped by the agglutinated red blood cells were collected by washing with saline. The separated trypanosomes were then washed twice with cold glucose saline and concentrated into a suitable volume. The trypanosomes were killed by rapid freeze-thawing. The killed trypanosome suspension (which constitutes the antigen) was pale pink to red in colour, depending on the numbers of red blood cells which it contained. It was stored at −20° until used.

Many substances were examined for adjuvant action, the results of which will be described in a later publication. In this communication, results with three substances are described: (1) *Quillaia* saponin, (2) a quaternary ammonium surface active agent, 'Arquad 2HT', (3) an alkylamine, *n*-hexadecylamine. Solutions or suspensions of these substances in water were prepared containing 1 mg/ml., 5 mg/ml. and 5 mg/ml., respectively. Mice were immunized against *T. congolense* by injecting subcutaneously a mixture of 0.1 ml. trypanosome antigen (equivalent to 1.0×10^6 trypanosomes) and 0.1 ml. of adjuvant solution or suspension. Two doses of vaccine were given with 14 days between doses. The mice were challenged by inoculating 1.0×10^5 trypanosomes subcutaneously, 14 days after the last immunizing dose. The *T. cruzi* vaccine consisted of a mixture of 0.1 ml. antigen (equivalent to 6.0×10^5 trypanosomes) and 0.1 ml. adjuvant. Groups of 9 or 10 mice were immunized with *T. cruzi* vaccine in the same way as with *T. congolense* vaccine and were challenged with 2.0×10^5 *T. cruzi* trypanosomes. The strains used were *T. congolense* strain *NIMR* and *T. cruzi* strain *Y*. After challenge, the tail blood of each mouse was examined microscopically for trypanosomes. Microscopical examinations were started 3–5 days after challenge and repeated thereafter 3 times per week.

The results with *T. congolense* (Table 1) and *T. cruzi* (Table 2) show that whereas the antigen or adjuvants given separately had no protective effect, the mixture of antigen and adjuvant provided a considerable degree of protection in mice. With both *T. congolense* and *T. cruzi* antigen, saponin proved to be the best adjuvant. The *T. congolense* vaccine gave a sterile immunity in 5 out of 6 mice, and the *T. cruzi* vaccine increased the survival time and decreased the parasitæmia. A sterile immunity was not achieved with *T. cruzi* vaccine.

Table 1. Protection of Mice against *Trypanosoma congolense* Challenge

Treatment	Mean pre-patent period, days (max. = 24)	Proportion of negative survivors at 10 days
None	7.1	1/7
'Arquad 2HT' alone	4.4	0/7
n-Hexadecylamine alone	4.8	0/6
Saponin alone	6.2	1/6
Antigen alone	5.0	0/7
Antigen + 'Arquad 2HT'	6.6	1/7
Antigen + *n*-hexadecylamine	16.1	4/7
Antigen + saponin	21.2	5/6

Table 2. Protection of Mice against *Trypanosoma cruzi* Challenge

Treatment	Mean survival time, days (max. = 33)	Mean parasitæmia*
Exp. 1		
None	12.4	186
Antigen alone	11.5	183
Antigen + 'Arquad 2HT'	18.4	107
Antigen + *n*-hexadecylamine	12.8	70
Antigen + saponin	19.3	72
Exp. 2		
None	15.0	128
Saponin alone	10.3	203

* Mean parasitæmia = number of trypanosomes seen in 20 microscopical fields (× 10 ocular, 4-mm objective) at height of infection per mouse.

Freund's adjuvant, with or without killed mycobacteria, was not effective with *T. congolense* antigen. No adjuvant activity was observed with potash alum.

The duration of protection conferred by *T. congolense* vaccine was tested by rechallenging the surviving mice at suitable intervals. Twelve weeks after the last immunizing dose of vaccine, 11 out of 22 mice were immune to infection with the same strain of *T. congolense*. At 19 weeks, 4 out of 6 mice were immune. The residual protection was further tested by injecting 1.0×10^6 trypanosomes of a different strain of *T. congolense* (*Buswale*). In this group of mice, 19 weeks after vaccination, 2 out of 5 animals remained immune to challenge.

Antigens, other than those derived from *T. congolense* or *T. cruzi* trypanosome cells, were examined for protective effect when mixed with adjuvant. Plasma or serum collected from mice heavily infected with trypanosomes but itself free from trypanosomes, injected with adjuvant in the same way as trypanosome antigen, protected against challenge. With *T. cruzi*, the plasma antigen (equivalent to Weitz's exo-antigen[4]) was more effective than trypanosome antigen. With the plasma antigen the average parasitæmia was 5 per 20 fields, compared with 272 in the untreated controls. 2/8 mice remained free from trypanosomes. The crithidial forms of *T. cruzi* grown *in vitro* and the culture medium therefrom, were found to have considerable protective effect.

Other flagellates zoologically related to *Trypanosoma* were examined for protective properties when prepared in the same way as the trypanosomes and mixed with adjuvant. No cross-protection was seen against *T. congolense* challenge, but some degree of cross-protection was observed against *T. cruzi* challenge. Protection against *T. cruzi* challenge was observed with *Crithidia fasciculata* and *Leptomonas collosoma* and, to a much smaller degree, with *T. melophagium* and *T. mega*. The culture medium in which *C. fasciculata* and *L. collosoma* had grown also showed a protective effect against *T. cruzi*.

The experiments have shown that the addition of adjuvants to weak antigens from trypanosomes and related protozoa can increase resistance to challenge in mice. Further details of these experiments will be published shortly elsewhere.

Prolongation of Homograft Survival in Mice with Single Doses of *Cyclo*phosphamide

IT is customary, in prolonging the survival of homografts with a chemical agent, to give frequent doses of the agent over a prolonged period Effective agents are generally toxic, and their use is attended by considerable mortality, in both laboratory animals and man The immune response is not uniformly susceptible to inhibition by these agents throughout its course[1], nor is it uniformly active It is likely, therefore, that dose-schedules not closely adapted to this changing sensitivity and activity of the immune response may, on one hand, subject the recipient to unnecessary toxicity and, on the other, fail to attack the immune response sufficiently during its most vulnerable period It is therefore of some importance to establish the principles on which optimum dose-schedules may be based

The complexity of this problem necessitates a stepwise approach Initially we have investigated whether a single dose of a drug can significantly prolong the survival of a homograft and whether there is an optimum time for administering this dose

Tail or abdominal skin from ($C57Bl \times A2G$) F_1 hybrid male mice was grafted on to suprapannicular beds on the chest wall of male *A2G* recipients The animals weighed 14–22 g at the start of the experiment The drug chosen was *cyclo*phosphamide, since we found it to have the highest therapeutic index of several effective agents when used to suppress the antibody response to a bacterial vaccine[2]

At various times before or after grafting, recipients were given *cyclo*phosphamide, 200 mg/kg subcutaneously, dissolved in physiological saline, 1 ml /20 g body-weight Grafts were first inspected 9 or 10 days after grafting and then every 1–2 days thereafter The end-point adopted was the time of complete breakdown of the graft

The results are shown in Fig 1, from which it appears that a single injection of *cyclo*phosphamide is maximally effective in prolonging the survival of homografts in the mouse if given at any time from shortly after grafting to about the 4th day afterwards Administration before grafting, or on the sixth day, has relatively little effect The results are analysed statistically in Table 1

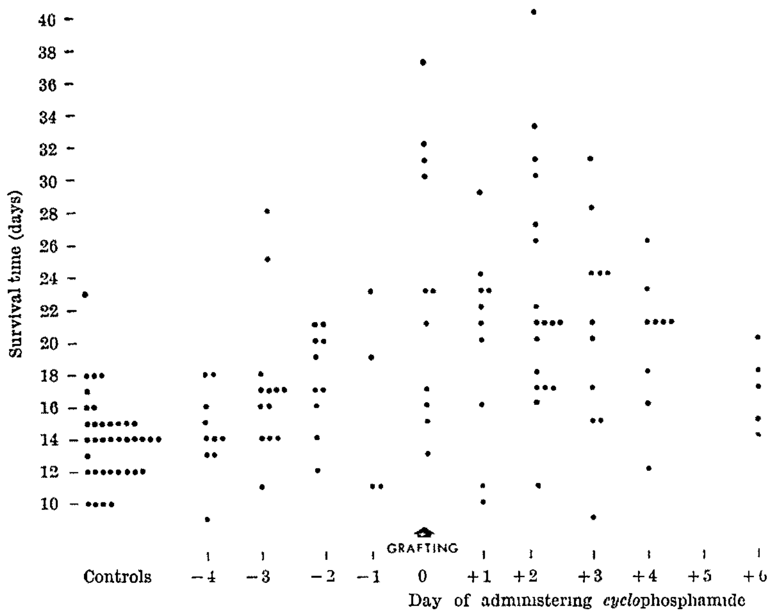

Fig 1 Effect of single doses of *cyclo*phosphamide on survival of homografts Points indicate animals in which grafts were completely rejected at the time shown in the ordinate Recipients were grafted on day 0 The *cylco*phosphamide injection on day 0 was given 1–2 h after grafting

Table 1 EFFECT OF SINGLE DOSES OF *Cyclo*PHOSPHAMIDE ON SURVIVAL OF HOMOGRAFTS

Group	Controls	–4	–3	–2	–1	0	+1	+2	+3	+4	+6
Mean survival time (days)	14 1	14 4	17 2	17 7	16	23 5	19 9	22 7	20 7	19 9	16 8
No	37	10	13	10	4	11	10	18	11	9	5
Variance	6 66	6 7	20 9	9 34	36	64 1	35 2	51 7	47 8	16 6	5 7
P*	—	> 0 5	0 02–0 05	0 002–0 01	> 0 5	0 001–0 002	0 01–0 02	< 0 001	0 01–0 02	0 002–0 01	0 05–0 1

* The significance of each difference from controls was determined by a modified *t*-test, taking into account the differing variances

We have also found that a single injection of 200 mg/kg *cyclo*phosphamide given 2 days after grafting to *A2G* recipients bearing grafts of *C57Bl* skin prolonged the mean survival time from the normal of 12 0±2 2 days to 17 0 ±2 3 days This difference is highly significant ($P = < 0\ 001$) A single injection, therefore, given at the appropriate time, significantly prolongs homograft survival even in the presence of strong *H2* incompatibility In further experiments we hope to find the optimum times of injection of two or more doses of drug

PATHOLOGY

Action of Tumour Growth and Tissue Products on the Zonal Distribution of Liver Glycogen in Rats and Mice

IN 1947, Young *et al* [1] reported a decreased deposition of glycogen in the livers of tumour-bearing mice given a glucose load after a fasting period Goranson *et al* [2] were unable to demonstrate any real difference in the levels of liver glycogen in fasted controls and tumour-bearing rats and showed that the phosphorylase activity in the liver was about the same in both groups On the other hand, the blood sugar-levels of tumour-bearing animals according to Goranson *et al* [3] is reduced in alloxan-induced diabetes As pointed out by Boyd *et al* [4] the carbohydrate metabolism in human beings may be abnormal in malignant disease These authors demonstrated a decrease in glucose tolerance in cancer patients which was reversed to normal by treatment with œstrogens

It has been suggested that the disturbance of the carbohydrate metabolism in tumour-bearing individuals, including the low liver glycogen deposition, is due to the shunt of available glucose to the tumour on account of its high glycolytic rate[5,6]

We studied the zonal distribution pattern of the glycogen in the livers of rats and mice bearing tumours or injected with tumour and normal tissue supernatant and now report our results

Male Wistar rats, weighing 150–200 g, were implanted subcutaneously with the

Yoshida sarcoma and killed 2, 3, 5, 7, 9, 12 and 15 days after the implantation. Rats bearing the Yoshida sarcoma in ascitic form were killed 2, 3, 4 and 7 days after the intraperitoneal passage.

Male Swiss mice bearing the Ehrlich ascites tumour were killed 2, 3, 5, 7, 9, 12 and 18 days after the intraperitoneal passage.

The tissue supernatant was prepared in the following way: fragments of the Yoshida sarcoma or of the normal tissues to be tested were homogenized with 20 ml. of chilled saline solution in an electrical blender for 3 minutes. The resulting homogenate was centrifuged at 20,000 r.p.m. (Spinco *L*-rotor 30) for 20 min at 10°. The supernatant was removed and injected into the subcutaneous tissue of the back of each animal in the dose of 3 ml. for the rats and 1·5 ml. for the mice. The normal organs tested were liver and kidneys.

Another group of animals was injected with cell-free ascitic fluid from either Yoshida or Ehrlich tumour in the dose of 2 ml. for the rats and 1·5 ml. for the mice. The injections were always homologous. A control group of rats and mice was similarly injected with saline. The injected animals were killed at 2, 6, 18 and 24 h after the injection.

The distribution of liver glycogen in tumour-bearing animals, either in solid form or as ascites, is conspicuously different from the normal. When fully established the alteration consists in disappearance of glycogen from the periportal area and decrease in the cells of the centro-lobular zone. With rats bearing the solid Yoshida sarcoma the change is seen as early as 2 days after the transplantation. During the whole period of observation (15 days) no other change is superimposed and the liver picture is about the same as that found at 2 days. With the Yoshida ascites tumour the alteration was not detected until 4 days after the intraperitoneal transferring and was consistently more intense than that observed in the animals with the solid form of the growth. A noticeable individual variation regarding the amount of glycogen mobilization was present in the animals bearing the solid form and was less evident with the ascites tumour. Very few animals showed a nearly complete depletion of glycogen throughout the whole liver.

The Ehrlich ascites tumour-bearing mice killed from 5 days up to 18 days after the intraperitoneal passage showed remarkably constant and uniform depletion of glycogen from the periportal area and decrease in the centro-lobular zone. The individual variation was negligible in this group.

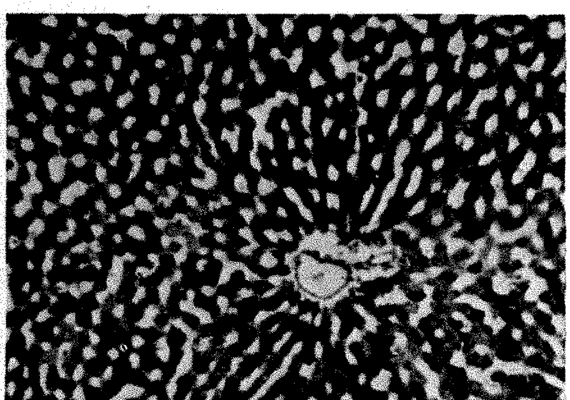

Fig. 1. Normal liver showing the even distribution of glycogen. Periodic acid-Schiff method. (× 150)

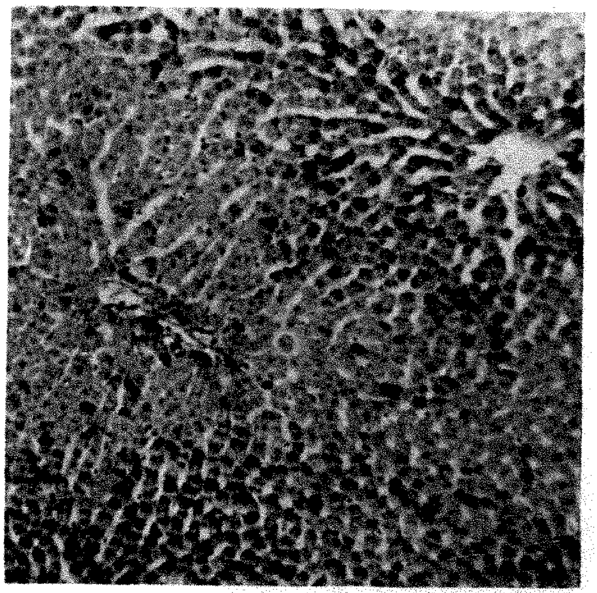

Fig. 2. Changed liver. Depletion of glycogen in the periportal area. Diminution in the centro-lobular area. Periodic acid-Schiff method. (× 150)

Rats and mice injected with homologous cell-free ascitic fluid, tumour supernatant and normal tissue supernatant also exhibited periportal glycogen depletion and centro-lobular diminution. The effect was not observed at 2 h, was irregularly seen at 6 h and was fully established at 18 h after the injection. The effect seems to be a short-lived one since at 24 h after the injection the normal glycogen distribution was again present in the treated animals.

Fig. 1 is from rat liver and shows the usual uniform distribution of glycogen.

Fig. 2 exhibits the described periportal depletion and centro-lobular diminution of glycogen observed in our experimental groups. The histological picture is reproduced in all experimental animals, either rats or mice. The animals injected with saline never showed any alteration in their liver glycogen distribution.

The observation that the glycogen depletion in the livers of rodents treated with tumour supernatant is in every way similar to that found in tumour-bearing animals invalidates the suggestion that this phenomenon is only concerned with the demands of a growing tumour for the available body glucose. On the other hand, the finding that the administration of either tumour or normal organ products can induce the same pattern of glycogen mobilization indicates that no specific tumour agent in the manner of a postulated toxo-hormone[7,8] is responsible for the observed alteration. Rather, it seems that this effect is part of a non-specific stress reaction against cell products overload, as has already been pointed out by Hilf *et al.*[9]. Perhaps the terminal cachexia of the animals bearing these tumours may be explained on terms of a chronic stress situation of which the liver glycogen change is a significant component.

BIOLOGY

Growth-rate of Mice in Static Magnetic Fields

EXPERIMENTS of the influence of a static magnetic field on the growth of mice were started in 1948 at the University of Budapest. I placed one half of a litter of six mice, for a period of four weeks, in the vertical field of an electromagnet and the other half of the litter in an identical dummy magnet. The aluminium cages were 38 mm in height and 75 mm in diameter, with hard rubber bottom and surrounded by an open tray, where food and water were provided. A forced air blow prevented the mice from staying for long periods outside their cage. They never attempted to escape, hereby proving the adequacy of their housing conditions.

The mice were conditioned for four days to the confinement before the magnet was energized. The field strength at the centre of the cage was 5,900 œ with an average gradient of 100 œ/cm. As can be seen from the weight curve, shown in Fig. 1, the field retarded the growth of the mice. We may note a sharp minimum on the third day, which seems to be the result of a shock due to the field, from which they shortly recover. If we disregard this minimum, the growth-rate does not start to decrease during the first few days; thereafter, however, the weight of the mice in the magnet significantly lags behind that of the litter-mate controls. The one male mouse started to lose weight on the eleventh day in the field and died shortly thereafter. This 'lethal' effect of the magnetic field on males has been observed several times since then[1] and is a phenomenon worth further investigation. The females did not exhibit any adverse symptoms. Removed after four weeks' residence in the field they mated, and gave birth to healthy litters 20 days later. (The normal gestation period of mice is 20 days.)

It is well known that there are many factors which can influence the growth-rate of mice. It is conceivable that the magnetic field acts via one or another of these factors; but it cannot be excluded that a magnetic field slows down mitotic activities in general. In the latter case, we would expect that the retardation-rate would increase with the mitotic activity of the tissue or organ in question, as is the rule with other external inhibiting agents. For this reason I investigated in 1948 and since then the effect of the magnetic field on the development of embryos in the uterus of mice and on the growth of transplanted and spontaneous tumours in mice. The observations support the foregoing assumption[1].

The effect of the magnetic field on the growth-rate of young mice is an effect which is far less sensitive to environmental conditions than most other effects, if comfortable housing conditions are provided and the position of the animals does not change relative to the magnetic vectors.

From about 20 physical phenomena, which occur in organisms placed in static magnetic fields, all with the exception of two (joule heat of induced currents and the heat generated in paramagnetic substances as a consequence of the alignment of dipoles against thermal agitation) are vector phenomena. The cumulative physical effects resulting from these phenomena, responsible for the triggering of biomagnetic effects, are, therefore, reversible effects. A frequent change in the position of the specimen relative to the field vector, or relative to the gradient vector, will lead to an attenuation, eventual annulment of the cumulative physical effect and, with it, to the disappearance of the biological effect itself. It is, however, not necessary to restrain mice in order to avoid a change in the position of the animal relative to the field. It is enough to place them in vertical fields, since mice seldom take supine positions.

During the past years further experiments have been performed with ten Alnico permanent magnets of 275 lb. each. The cages were 3¾ in. in diameter and 1½ in. high, with plastic bottoms, food and water supply, and connected to inclined exercise galleries. Two types of fields were used: in one the field strength was 4,200 œ with an average gradient of 80 œ/cm (called in the following 'homogeneous'); in the other the field strength was on average 3,600 œ and the gradient at the centre of gravity of the mouse 650 œ/cm (called in the following 'inhomogeneous'). The dummy magnets were simulated by 2-in. thick iron pole pieces, to avoid effects caused by the biological effect of cosmic radiation[2]. The dummy cages were located 2 ft. from the magnet cages, but shielded against the stray field of the magnets. The cages were cleaned by the tail movement of the mice and every second day washed in an automatic washer.

For weighing purposes the two or three mice housed in the same cage were transferred to a plastic cup and weighed with the cup. However, the error in weight, due to loss in fæces and urine, is negligible, even if the weighing is done without a cup. One droplet from a full-grown mouse weighs only 65 mg, and well-treated mice, used to the person handling them, never urinate during the weighing process. A considerable error can, however, be introduced

if weighing is carried out during or around the normal feeding time of the mice. The weight of a mouse can be 2 g higher in the morning than in the evening, and since mice usually feed in groups, some amount of difference may arise between magnet and dummy groups. I have, therefore, investigated the weight variation of mice over a 24-h period, as well as recorded with electric devices their feeding habits. Their main feeding time lies between 11 p.m. and 5 a.m. and young mice have a second snack between 8 a.m. and 11 a.m. However, in the afternoon, between 2 p.m. and 6 p.m., the mice rest. Measuring the weight of a larger group of mice, individually, day by day around 4 p.m., revealed that the daily weight fluctuation does not exceed 0·55 g by young and 0·49 g by old mice. This fluctuation strictly follows a Gaussian distribution, implying that in a series where 30 animals are treated and 30 are used as controls the difference in the growth-rate can be established with an accuracy better than 0·20 g.

Table 1 shows the results of one of the series in which 30-day-old mice were treated in a homogeneous field. The first column contains the total weight of three mice per cage before placing them in the field; the second and third column, the weight on the tenth and twelfth days in the magnet, and the fourth column, the weight difference up to the eleventh day. Columns 5–8 contain the same results for the dummy groups. We can see that the average growth was 5·74 gm for the mice in the magnets and 8·33 gm for the mice in the dummy magnets. The difference in growth-rate during the first 11 days is therefore 2·59 ± 0·68 g; the effect is significant on a probability level of 1 : 1,560.

We see, furthermore, that the individual variance of the magnet group is almost twice the variance in the dummy group, indicating that the magnetic field affects individual mice to a different degree. For example, the three mice in the fourth row seem not to have been affected, while the effect of the field was twice the average in the group of the sixth row.

Twelve similar series were conducted with a total of 680 female mice. The results are summarized in Table 2 according to strain, age and field used. The growth differences up to the eleventh day of residence in the field are tabulated together with their standard errors. We can see that the total difference in weight of young mice is larger than that of older mice. The relative decrease of the growth-rate is, however, greater for the older. Young mice do not stop growing in fields of such magnitude, whereas older mice sometimes may lose weight.

Fig. 2 shows the daily change in weight of the pooled results of nine series, in which Swiss female mice were treated in homogeneous and inhomogeneous fields respectively. We can see that the effect of the homogeneous field is far greater than that of the inhomogeneous field. In both cases the minimum occurs around the tenth day of residence. We may again note the minimum around the second day, followed by a recovery, as already noted on Fig. 1. This phenomenon is now under further investigation.

I wish to express my thanks to my wife, for her help in conducting these experiments and for many discussions. This work was supported by the Biomagnetic Research Foundation.

Phytoplankton Production in the South-eastern Pacific

THE distribution of phytoplankton concentration and its photosynthetic rate in the surface waters of the south-eastern Pacific are shown in Figs. 1 and 2. Measurements were made during the following cruises: *Costa Rica Dome*, November–December 1959; *Step-I*, September–December 1960; *Swansong*, October–December 1961; and the cruise of the *Esmeralda* (Chilean Navy), July–August 1962.

The concentration of chlorophyll *a* (refs. 1, 2) was used as an index of standing stock of surface phytoplankton; the production of the phytoplankton was measured by the carbon-14 method[3] under natural light at surface temperatures.

Greater phytoplankton concentrations and production exist in regions of divergence, vertical mixing, shallow

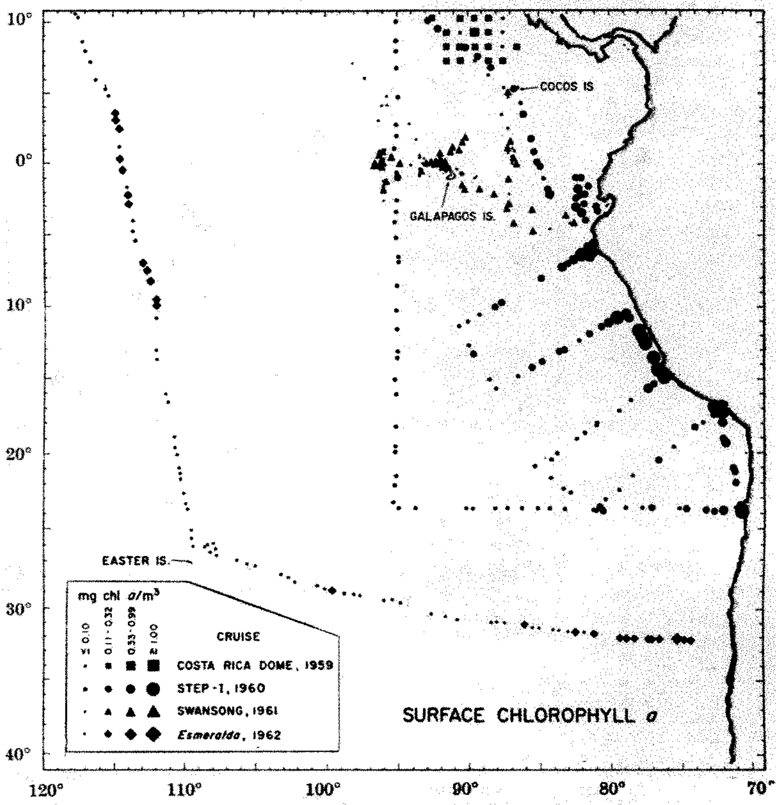

Fig. 1. Distribution of chlorophyll *a* at the surface in the south-eastern Pacific

mixed layer, or where enriched surface water is driven by wind. High production occurs along the Peruvian coast owing to replenishment of plant nutrients by strong upwelling. Because the Peruvian anchovy feeds directly on this rich source of phytoplankton it is able to exist in such numbers that guano birds and fishermen took 10 × 10^6 tons in 1962.

Production is relatively high between the Galapagos Islands and the coast, apparently the result of enriched surface water from coastal upwelling off northern Peru being driven to the north-west by the prevailing south-easterly winds. Off central and southern Peru these prevailing winds increase in force seaward. The seaward increase of the resulting Ekman transport causes a divergence reflected in moderate offshore production.

Off central Chile the prevailing southerly winds in August decrease in force westward so no divergence can be expected as off Peru, but Ekman transport may carry enriched surface water westward from the coastal upwelling regions. The divergence between the Peru Oceanic Current[4] and the Peru Counter Current[4] may also contribute to this wide zone of moderate production.

At the Costa Rican Thermal Dome[5], centred at 9° N., 89° W., upwelling and a shallow mixed layer enable production to be considerably greater than in surrounding waters.

Equatorial upwelling and vertical mixing between the South Equatorial Current and the sub-surface Cromwell Current explain the high production found near the equator. The shallow mixed layer along the north boundary of the Counter Current and along the equator, and the divergence[4] between the South Equatorial Current and southern edge of the South Equatorial Counter Current[6], all may contribute to the increased production of the region between 10° N. and 10° S. This productive strip in the eastern tropical Pacific is exploited by the Japanese long-line fishermen, who obtain best catches of tunas and billfishes there, and concentrate their effort within these limits.

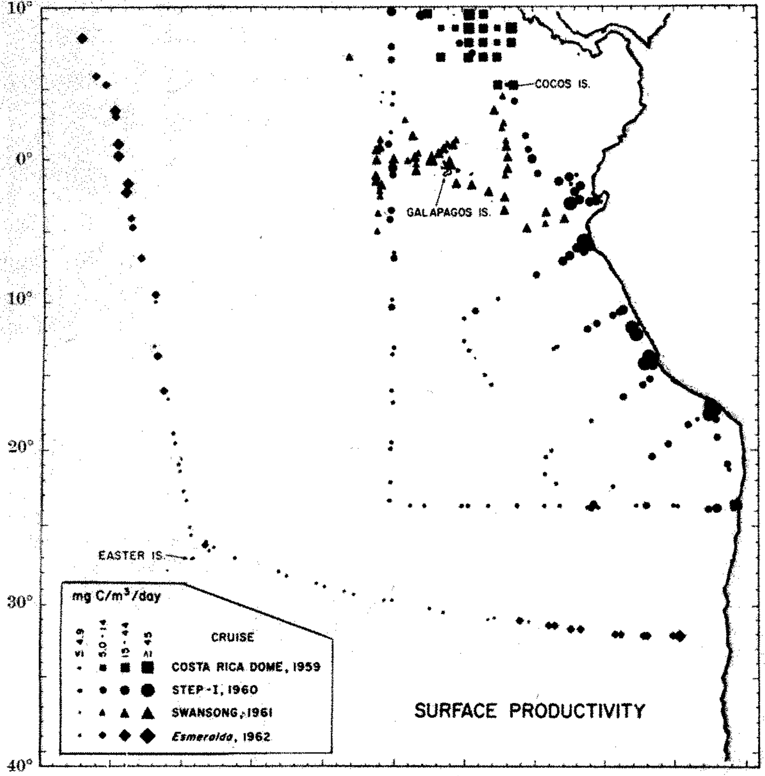

Fig. 2. Distribution of the rate of carbon fixation by photosynthesis at the surface in the south-eastern Pacific

Toxic Properties of the Saliva of *Cassis*

THE large gastropods of the genus *Cassis* feed on various achinoids[1]. Despite its toxic sharp spines, even the black sea urchin, *Diadema antillarum*, is the prey of the helmet conch, *Cassis tuberosa*. The feeding habits described by Schroeder[2] show that *C. tuberosa* actively pursues the urchin and appears to overwhelm it physically, despite the phalanx of spines that *Diadema* brings to bear on any point of attack. Even for the tough-footed *Cassis*, this is a *tour de force*, since the microneedle points of the spines readily pierce the sole of the foot. One wonders whether the helmet is quite as reckless as first appears, or whether he is aided by tricks other than a headlong charge. Schroeder also reports " . . . its long proboscis may be seen greedily feeling among the spines for the urchin's body". *Cassis* also everts his proboscis when he is broken from his shell, and then usually squirts a jet of clear fluid in different directions as he whips his proboscis about. This saliva is toxic to numerous marine organisms and conceivably could be used offensively as well as defensively. The work recorded here was undertaken to show the manner in which the poison acts on *Diadema*.

Small urchins (3–4 cm body diameter) were immersed in saliva (lot *B*) diluted 1/1,000, 2/1,000, and 4/1,000 (total volume 250 ml., excluding the volume of the urchin). There was immediate pigment release and violent waving of the spines. Movement was co-ordinated, however, and the urchins repeatedly climbed the side of the finger bowl. At the end of 20 min all three had lost the response to shading. The different doses showed a graded response to touch: when spines were lightly touched, the urchin in 1/1,000 responded by converging spines towards the point of contact; 2/1,000 yielded only general unco-ordinated spine movement, and the urchin in 4/1,000 responded only when the body was prodded. Continued prodding induced spine-waving at successively farther distances from the point of stimulus. The response to increased light (as against shadow) was also blocked in the two highest doses, in one test after exposure for 30 min. When placed in direct sun, all but the urchin at 4/1,000 began to wave their spines, and those in the control and bottom dose moved about the dish. Recovery was detectable at 1 h in the two lowest doses and was complete at 4·5 h. A second urchin placed in the previously used 2/1,000 dilution showed no suppression of reactions or of spontaneous movement.

Isolated body wall of *Diadema* placed in diluted *Cassis* saliva showed the same sequence of sensory suppression in relation to time and dose as did the intact urchin. Response to shading was lost first, then the spine convergence response to a lightly touched spine, and finally all response to even strong prodding. High concentrations evoked pigment release initially, and finally suppressed all spontaneous movement. Fragments left in the weak solutions eventually recovered.

Saliva lot *B* can be taken as an example. At 4/1,000 there was an immediate release of pigment and increased waving of spines. In three minutes the response to shading was lost in concentrations of 4/1,000, 2/1,000, 1/1,000, and 0·5/1,000. The response to prodding disappeared in 6 min at 4/1,000, in 38 min at 2/1,000, and was not lost at 1/1,000. In another series, saliva (lot *A*) decreased the response of fragments to shadow and touch in dilutions as great as 4/10,000. There was a questionable depression at 3/10,000. By means of small doses it was not possible to block the light response alone. The effect of the toxin at any effective dilution progressed and then declined, so that a level state at any one stage of inhibition was not attainable.

The spontaneous recovery of fragments under supposedly continuous exposure was subjected to further analysis. Such fragments transferred to fresh solutions were again affected. Untreated pieces placed in the old solution were inhibited little, or not at all. Dilutions in sea-water left at room temperature retained their activity, however, if not in contact with *Diadema*.

Cassis tuberosa has large paired salivary glands comprising a large hyaline posterior portion from which a duct passes through the smaller brown opaque anterior lobe. An aqueous brei of these glands inactivates *Diadema*, so the gland is indicated as the source of the toxin. The other two species of *Cassis* on Bimini, *C. madagascarensis* and *C. flammea*, also have large paired bilobed salivary glands with toxicity comparable with the glands of *C. tuberosa*.

The helmet conch is supplied with a poisonous saliva capable of incapacitating the surface organs of the black urchin and thereby decreasing his mobility and the effectiveness of his spines. It would now appear that the play of the proboscis among the spines of the urchin, as described by Schroeder[2], serves to deliver the poison to the body surface, where it is most effective.

The saliva blocks response to touch and to all the different responses to light: spine convergence on a shaded area, inhibition of spine movement under steady illumination, and increased movement under increased light[3].

The active principle of the saliva would appear to be a neurotoxin, since it first inactivates the sensory receptors or their afferent nerves. Receptors cannot be distinguished morphologically from nerves, but the physiological evidence points to a sequence of events in the receptor-effector arc[4]. The systems responding separately to mechanical and actinic stimulation[3] are separately affected by the toxin. It can block photoreception temporarily without interfering with the tactile sense, or with transmission of the impulse throughout the body. Below a damaging level, the effect is reversible, even when it has proceeded to the extent of eliminating all response and all spontaneous movement. Immobilized pieces placed in fresh sea-water regain activity in a few minutes. The urchin, or even a piece of the body wall, can inactivate the poison. Ascribing this inactivation to bacterial decomposition would appear unjustified, since the saliva is antibiotic, and solutions allowed to stand at room temperature maintain full toxicity for 24 h. Loss of activity is accompanied by a drift towards neutrality (the saliva is strongly acid), but saliva initially neutralized retains its paralysing properties.

Long-distance Migration of Atlantic Salmon

In recent years reports have appeared[1–4] of Atlantic salmon bearing English or Scottish tags being caught on the west coast of Greenland, and Atlantic salmon tagged in Canada[5] have also been caught in the same area.

Two further records are now to hand, both in respect of salmon tagged as smolts at this Ministry's research installation on the River Axe, south Devon.

The first, a male, was tagged on April 20, 1960, and was recaptured off Sukkertoppen (65° 20′ N., 53° 00′ W.) on October 26, 1961, length 73 cm and weight 4 kg. The second, a female, was tagged on April 11, 1961, and was recaptured near Kangerdluarssorujak (60° 40′ N., 45° 45′ W.) in the Julianehaab District of west Greenland on November 19, 1962. It was then 94 cm long and weighed 4·7 kg.

The minimum distance travelled by the first fish (the longer journey) was approximately 2,300 miles from the point of tagging to the point of recapture.

Nielsen[2] states that the duration of the freshwater life, before migration as smolts, of the west coast of Greenland salmon catch indicates that these salmon are, for the most part, of more southern, non-Greenlandic origin. As increased numbers of smolts were tagged in English and Welsh rivers last year further recaptures off Greenland of British-tagged fish are anticipated this autumn.

We thank the Ministry for Greenland, Charlottenlund, Denmark, for sending details of the recaptures.

Hexagonal Patterns in Cell Membranes

Dourmashkin, Dougherty and Harris[1] demonstrated a hexagonal pattern on some viral and mammalian membranes treated with saponin. They took the view that the pattern was revealed by the removal of certain lipid components and suggested that their observation supported the mosaic structure proposed for cell membranes by Parpart and Ballentine[2] in which lipid cylinders, 90 Å in diameter and spaced at 150 Å centre to centre, are enclosed in a protein mesh. Muir[3] has produced the same effect in the plasma membrane of rat intestinal epithelium by *in vivo* treatment with saponin.

Kavanau[4] has proposed, on the basis of other evidence, a new theory of membrane structure and function based on the concept of a hexagonal mosaic arrangement of the lipid component in discrete bimolecular leaflets which can transform to a more open arrangement of cylindrical columns under prescribed conditions.

Bangham and Horne[5] and Glauert, Dingle and Lucy[6], however, have shown that patterns like those of Dourmashkin *et al.* can be induced in monolayers of cholesterol and in mixtures of cholesterol and lecithin by treatment with saponin. These authors suggest that their figures are formed by the insertion of saponin molecules into the film. Husson and Luzzati[7] also, using X-ray diffraction techniques, have shown that in saponin-treated red cell membranes a hexagonal lattice of 165 Å spacing can be detected, whereas only a lamellar structure is shown in cell membranes prepared by the use of hypotonic phosphate. They conclude that their results argue against an intrinsic pattern in the normal membrane.

In a recent investigation[8] of the fine structure of the marine protozoan *Gromia oviformis* we were unable to find a normal cell membrane. Instead, we found at the cell

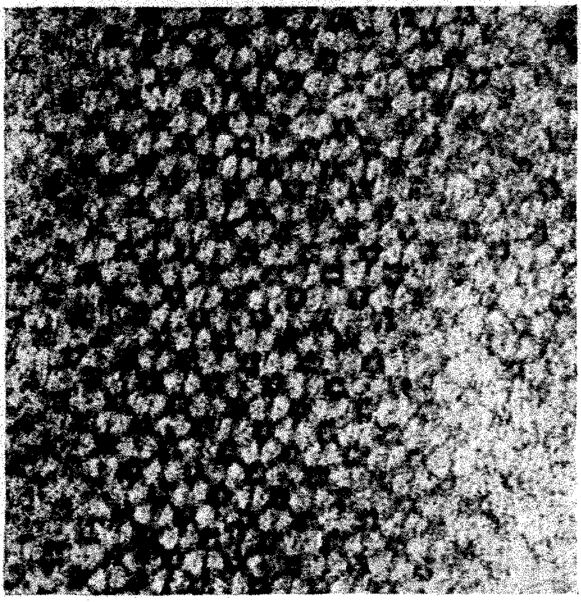

Fig. 1. Electron micrograph of tangentially sectioned 'honeycomb membrane' of *Gromia oviformis*, showing the hexagonal pattern. (× 280,000)

surface a number of layers which for convenience of reference we called 'honeycomb membranes'. These exhibited in tangential sections, Fig. 1, a hexagonal array of hollow cylinders about 100 Å in diameter, each containing a central hole of 30 Å diameter, with a centre to centre spacing of 210 Å. Linking septa connected each cylinder to its neighbours. In cross-section it was apparent that up to ten membranes were included in the complex. Kavanau has referred to this as possibly representing a case of a membrane locked in the 'open' configuration by structural modifications. We would like to emphasize one or two points which may be relevant.

Following the demonstration by Luzzati and Husson[9] of similar structures as transitional phases in lipid-water systems we have entertained the idea that the honeycomb membranes might represent a high permeability state of a normal cell membrane in response to some physical or chemical stimulus, but if this were so we are quite at a loss to say what could have induced it. Alternatively, we have considered the possibility that they might be an artefact arising during the course of fixation and embedding, but for this there appears to be no precedents, and, as far as we are aware, these processes proceeded normally. No saponin or other surfactant was used in the preparation, which was a straightforward fixation in Caulfield's solution with methacrylate embedding. Sections were stained with permanganate after mounting. Hence, it appears unlikely that the structure was produced by insertion of foreign molecules in the same way as those discussed by Bangham and Glauert.

The existence of the connecting septa between the cylinders of the *Gromia* membrane would appear to put difficulties in the way of direct transformation between the observed structure and the usual bimolecular membrane. Further, the conditions of fixing and dehydration were such as to favour Kavanau's 'closed' configuration. To this extent, then, we may say that the structure observed probably represents a stable condition, normal in the living animal. Unfortunately, no further animals were available with which to repeat the preparation; but on this occasion the structures were seen in two individuals embedded entirely and on the inner surfaces of two shells from which the cytoplasm had been dissected. This suggests that these membranes are a generally occurring feature in the species under consideration. The work of Wohlfarth-Bottermann[10] and our own unpublished observations on an allied organism, *Allogromia laticollaris*, indicate that it contains no such system, but a normal plasma membrane.

Since we were unable to demonstrate a normal plasma membrane in *Gromia*, whether the honeycomb structure is intra- or extra-cellular remains unresolved. It may be that it is more properly related to the cell wall mosaics shown by, for example, Houwink[11] in micro-organisms. Regardless of its precise position and function, however, it does represent an instance of molecular architecture apparently corresponding very closely to the membrane models proposed on one hand by Parpart and Ballentine, and on the other by Kavanau to account for the properties of such membranes in terms of their chemical composition.

Growth of Single Cells from Higher Plants on Synthetic Media

THAT isolated single cells of higher plants can develop into cell groups and tissues was first demonstrated by the use of 'nurse' cultures[1]. Recently single cells of higher plants have been more easily grown by a 'plating' method; although the step from the 'nurse' culture to the 'plating' technique has required the addition of complex components, especially of coconut milk, to the basic synthetic media[2]. Media supplemented either by coconut milk or by yeast extract have been used in all published successful experiments in which extensive cell divisions of isolated cells have been observed. Because we know almost nothing about the active principle or principles of coconut milk and since at least with certain tissues the appearance of polyploid cells is furthered by coconut milk[3], experiments were undertaken with the view of growing single cells on chemically defined, synthetic media.

The first experiments involved a relatively fast-growing strain of *Haplopappus* cultures, which has been grown since 1959[4] on 0·6 per cent agar media containing White's nutrient[5] and 2,4-D at a concentration of 5×10^{-9} g/ml. These cultures are soft and can be spread into single cells and small cell groups by means of a spatula. They were spread in this way on the surface of the agar medium in a sterile Petri dish. It was soon apparent that under these conditions cell division occurred only in the small cell groups—up to 5 and 10 cells and more—but not in the single cells. The results were better if the cultures were grown for 2 or 3 months in test-tubes on the same medium, but with the phosphate-level (sodium dihydrogen phosphate) raised from $1{\cdot}7 \times 10^{-5}$ to $8{\cdot}5 \times 10^{-5}$ g/ml., then transferred to Petri dishes with the same high phosphate medium to which was added gibberellic acid (10^{-6} g/ml.) and spread after a growth period of 10 days in the dishes. With this method divisions were observed in about 15 per cent of the single cells. This proved that isolated single cells are able to grow on synthetic media and, in

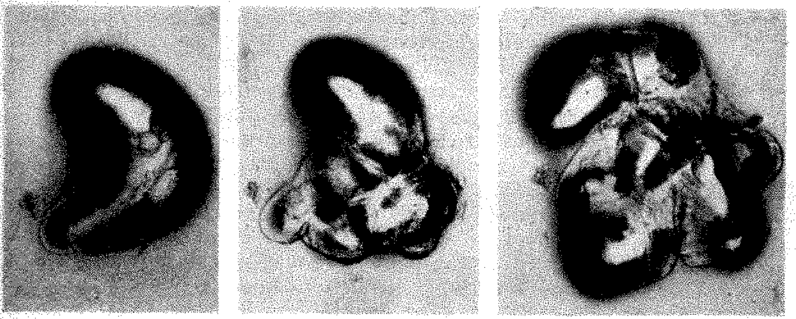

Fig. 1. Cell division in an isolated single cell of crown gall tissue of *Vitis vinifera* (× c. 125). (*a*) Single cell 8 days after isolation; (*b*) the same cell after 12 days; (*c*) 18 days after isolation

two out of 58 dishes, the formation of cell clusters (up to 50 cells) from such cells did occur. However, in most cases the *Haplopappus* cells turned brown and died after only one or a few divisions.

I therefore looked for a tissue which would spread as well as the *Haplopappus* cultures but in which this dying out of cells would not occur. A tissue answering this requirement is the crown gall tissue of *Vitis vinifera*[6], which grows excellently on a 0·7 per cent agar medium containing the macroelements according to Heller[7], Berthelot's solution of microelements[8], 5 per cent glucose and, in addition, vitamin B_1 (10^{-6} g/ml.). When using this medium, the upper parts of cultures (0·6 g) were transferred after a growth period of 8–10 weeks in test-tubes to Petri dishes and spread immediately; division of single cells could be observed (see Fig. 1 *a–c*) with an average plating efficiency of 40 per cent—in extreme cases even 70 per cent of the isolated cells divided. Some of these cells have now developed into tissue colonies of the normal size.

Although the division of the isolated *Vitis* cells occurs very regularly there are interesting variations in their behaviour. Usually division of the isolated cells starts during the first 12 days after spreading. However, others remain quiescent for between 30 and 50 days. Most of these quiescent cells were in regions of the agar free from other cells and cell groups and their division was found to occur as such regions of the agar became invaded with growing cells. It is therefore concluded that the initiation of division in such cells is dependent on them coming under the sphere of influence of actively growing cells.

I thank Prof. R. J. Gautheret of the Faculté de Science de Paris for providing me with the crown gall cultures of *Vitis vinifera*.

VIROLOGY

Variation of Interferon Yield with Multiplicity of Infection

CHIKUNGUNYA virus is one of the best inducers of interferon in chick cells, and many of the conditions which affect the yield of interferon have been elucidated[1,2]. This communication reports an investigation of the relationship between the amount of Chikungunya virus inoculated into chick cell cultures and the subsequent yield of interferon. Dilutions of Chikungunya virus were prepared and placed in bottle cultures of chick cells which were then placed at 37° for 24 h. Supernatant fluids were collected, heated at 65° for 30 min to inactivate the virus, and assayed for interferon using the procedure of Lindenmann and Gifford[3]. The PDD_{50}, defined as the amount of interferon preparation required to depress the plaque count to 50 per cent of the control value[3], was determined and plotted against the logarithm of the ratio of plaque-forming units/cell (Fig. 1). Less interferon was found to be produced by the cultures which received the greatest amount of virus than by those which were infected with approximately 0·1 plaque-forming units/cell. Even with 0·01 plaque-forming units/cell a considerable amount of interferon was produced. Three experiments have all given similar results. In other experiments fresh medium was placed on interferon producing cultures 24 h after infection and re-incubated for an additional 24 h. The amount of interferon found was usually less than 15 per cent of the first 24-h yield, indicating that most of the interferon was produced in the first 24 h after infection.

Similar titrations by Burke and Isaacs[4] using ultraviolet-inactivated influenza virus and chick chorioallantoic membranes showed no such zone of inhibition at high virus doses. These findings suggest that infection of cells with active plaque-forming virus inhibited the production of interferon. A comparison of the amount of interferon produced by stock preparations of Chikungunya virus with partially inactivated Chikungunya virus preparations was made and the results are given in Table 1. Considerably more interferon was produced by the partially inactivated preparation of virus than by the stock virus even though the same dilution of the virus preparation was utilized in both cases. It has already been shown that completely inactivated Chikungunya virus would induce the production of interferon in chick cells[5]. These results give evidence that interferon production by preparations of Chikungunya virus was due to 'inactive' virus in the stock preparations. It would be anticipated that conditions which tend to inactivate this virus would enhance interferon production. This would fit with the observation that the yield of interferon in an 11 h single cycle of growth of Chikungunya virus was higher at 42° than at 35° (ref. 2), since greater inactivation of the virus should occur at the higher temperature.

De Maeyer and De Somer[6] have demonstrated that production of interferon in rat tumour cells infected with Sindbis virus was inhibited at high multiplicities. Those results, as well as these reported here, may be related to

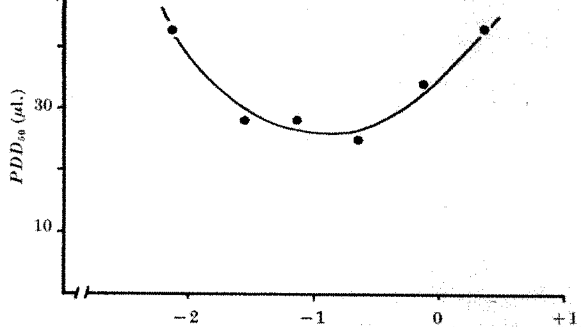

Fig. 1. Comparison of the resultant PDD_{50} of interferon with the logarithm of the input plaque-forming units/cell

Table 1. COMPARISON OF THE YIELD OF INTERFERON BY STOCK AND PARTIALLY INACTIVATED PREPARATIONS OF CHIKUNGUNYA VIRUS

Virus preparation	Plaque-forming units/cell	Total PDD_{50} units interferon produced
Stock virus	0·2	100
Partially inactivated*	0·01	186

* Stock preparation of Chikungunya virus was incubated at 35° for 4 h. Both preparations of virus were used at the same dilution.

the 'inverse interference' phenomenon described by Lindenmann[7].

Responses of Germ-free Mice to Friend Virus

CONSIDERABLE interest has developed in the germ-free animal as an assay system for potential oncogenic viruses. Theoretically it should provide a more uniform test system than the conventional animal with its unpredictable microflora which may influence unpredictably the response to the agent being studied. For this reason we undertook a comparative study of Friend virus infection in germ-free and conventional mice of the same strain. This communication concerns the results of this investigation.

The disease produced by Friend virus was first characterized by Friend[1] and later studied by a number of other workers[2-7]. Basically it consists of a neoplastic proliferation of reticulum cells with an associated erythroblastosis, polycythæmia and leucocytosis. The disease is invariably fatal in susceptible mice.

Flexible 'Trexler' plastic isolators were used for maintaining the germ-free environment. Their operation has been described by Trexler[8]. Germ-free mice (Hauschka-Mirand/*ICR* Swiss) were obtained from the Charles River Breeding Laboratories of Boston, Massachusetts.

The conventionalized mice referred to in this experiment were germ-free mice which had been purposely contaminated by placing fæces of open-animal-room mice in the drinking water. The conventionalized mice were maintained in isolators. The open-animal-room animals were mice of the same strain which were raised under ordinary laboratory conditions and were housed in open cages. These were also obtained from Charles River Breeding Laboratories.

Throughout this experiment, the germ-free and 'conventionalized' animals ate the same sterilized diet and were maintained in similar cages. Both groups were maintained in isolators and exposed to similar handling as a control of environmental factors other than fæcal microflora. The open-animal-room animals were housed in open cages but in the same room in which the isolators were located. They received the same diet as the other two groups. Weights and count determinations were made on a minimum of 10 animals per group.

Samples of diet, bedding, stools and water were regularly cultured as a check on the germ-free environment of the isolators. Routine microbiological testing was limited to a search for bacteria, fungus, parasites, and pleuropneumonia-like organisms. At the end of the experiment, the blood, cæcal contents, lung, liver and spleen from the germ-free mice were cultured as a final check on the maintenance of a germ-free environment.

Seven-week-old mice were inoculated intraperitoneally with 0·2 ml. of a cell-free filtrate prepared from the spleen of a Friend virus-infected mouse. Bacteriological studies of the filtrate were negative.

The investigations of uptake of iron-59 utilized the procedures previously reported[9]. The iron-59 solutions were checked for bacteriological sterility prior to administration.

Results showing the response of germ-free, conventionalized and open-animal-room mice to Friend virus are presented in Tables 1, 2 and 3. At 7 days no appreciable response was apparent in any group. However, at 14 and 21 days all infected groups showed some evidence of

disease but the response was considerably greater in the germ-free group as measured by splenic weight, hæmatocrit, and peripheral blood erythrocyte and leucocyte levels. The rise in erythrocyte level was accompanied by the appearance of erythroblasts in the peripheral blood and an increase in blood volume. Histological examination of the livers and spleens of all animals confirmed the greater severity of the disease in the germ-free group. However, the general pattern of the disease was the same as that described previously[3–7]. Perhaps it is of some interest to point out that the liver weights of germ-free mice were generally smaller than those of the conventionalized and open-animal-room mice.

In a previous investigation we found that the 24-h uptake of iron-59 by the spleen was an excellent parameter for following early manifestation of this disease because of its marked sensitivity as an index of erythropoiesis[9]. The results in Table 4 clearly show that the greatest increase in 24-h splenic uptake of iron-59 occurred in the germ-free group.

(*b*) Open-animal-room with virus	8·98 3·0–15·6

Additional data at 28 and 35 days post-infection also confirm the greater severity of the disease in the germ-free group.

These findings indicate that Hauschka-Mirand *ICR* germ-free mice are more sensitive to Friend virus infection than are conventional mice of the same strain. The enhanced susceptibility was reflected by a decreased latent period for disease production. There was no change in the basic pathological pattern of the disease. Similar studies are now under way with other murine leukæmia viruses. If the germ-free mouse proves to be generally more susceptible to leukæmogenic viruses than the conventional mouse, this could provide a valuable tool for the assay of potential leukæmogenic agents in mice.

This study was supported in part by U.S. Public Health Service, J. A. Hartford Foundation, and Atomic Energy Commission. We thank Miss Helen Fox for assistance, and also Mr. Peter Squicciarini and Mr. Michael McDougall, research participants, who were supported by the National Science Foundation.

Effect of Phosphate and Borate on the Infectivity of some Viruses during Purification

IN a method[1] developed in 1958 for purifying cucumber mosaic virus, infected tissue was homogenized in 0·5 M potassium phosphate buffer containing 0·1 per cent thioglycollic acid. To chelate possible metal contaminants in the phosphate, 0·001 M sodium EDTA was also added before the thioglycollic acid in subsequent tests. The filtrate was clarified by adding *n*-butanol (to an 8·5 per cent final concentration) and this was followed by low-speed centrifugation (30 min at 8,000 r.p.m. in the No. 30 rotor of a Spinco model *L* ultracentrifuge). The virus in the resultant supernatant was pelleted by ultracentrifugation (60 min at 30,000 r.p.m. in the No. 30 rotor), the virus pellets resuspended in 0·05 M phosphate buffer (*p*H 7·5) and the suspension finally clarified by low-speed centrifugation.

The same method, or with minor modifications, has been used recently for the purification of other viruses including cauliflower mosaic virus[2], potato virus *F* (ref. 3), alfalfa mosaic virus[4], celery yellow vein virus, tomato black ring virus and beet ring spot virus[5] and pelargonium leaf curl virus[6]. These viruses, except for potato virus *F* (ref. 7) and alfalfa mosaic virus[8], are spherical in shape like cucumber mosaic virus.

Attempts were made by me in 1960 to purify lettuce mosaic virus using the same procedure. These attempts were unsuccessful, the final preparations being non-infectious as indicated by the lack of local lesions on the leaves of *Chenopodium amaranticolor*.

By this time, Shepherd and Pound[9] had purified turnip mosaic virus using the cucumber mosaic virus method, but they reported that their final preparations were highly infectious only if resuspended in 0·02 M borate buffer.

Subsequent tests by me of this modification of the phosphate method failed to give infectious preparations of lettuce mosaic virus. It was then decided to substitute 0·5 M borate buffer (boric acid adjusted with sodium hydroxide to *p*H 7·5) for phosphate throughout the whole procedure and, when this was done, highly infectious preparations were made. The method has been briefly described[10] and has since been used repeatedly with the same result.

In addition to infectivity assessments, precipitin tube tests were made of the final preparations of lettuce mosaic virus purified in borate and phosphate against antiserum obtained by injection of rabbits with borate purified infectious virus. The borate preparations gave a strong precipitin reaction but the phosphate preparations gave little or no reaction.

As the phosphate method was known to be unsuitable for the preparation of the rod-shaped lettuce mosaic virus it was decided to compare the phosphate and borate methods for the purification of several viruses. Those chosen were the rod-shaped viruses causing lettuce mosaic, turnip mosaic, and potato mild mosaic (potato virus *X*), and the spherical viruses causing cucumber mosaic and arabis mosaic. The method was as follows. Two lots of tissue of similar infectivity were obtained by cutting infected leaves longitudinally. These were then homogenized (1·0 g of leaf per 1·5 ml. of buffer) in phosphate or borate buffer (0·5 M, *p*H 7·5) each containing 0·001 M sodium EDTA and 0·1 per cent thioglycollic acid. The subsequent purification procedure was the same as that described for lettuce mosaic virus except that the ultracentrifuge virus pellets were each resuspended in 0·5 ml. distilled water. The relative infectivity of the two types of final preparation at various dilutions was then determined by local lesion assay (or systemic infection in the case of arabis mosaic virus) after inoculation to *C. amaranticolor*. The results obtained with the five viruses are given in Table 1. All have been confirmed in several repeat experiments.

Table 1. INFECTIVITY ON *C. amaranticolor* OF FIVE VIRUSES AFTER PURIFICATION FROM PHOSPHATE AND BORATE HOMOGENATES

Virus and propagation host	Dilution of preparation	Mean No. of local lesions per half-leaf	
		Phosphate preparation	Borate preparation
Lettuce mosaic virus (lettuce)	undiluted	1	157
	1/10	0	57
	1/20	0	6
Turnip mosaic virus (turnip)	undiluted	2	286
	1/10	1	157
	1/20	0	24
Potato virus *X* (tobacco)	10^{-3}	6	48
	10^{-4}	3	10
	10^{-5}	0·1	7
Cucumber mosaic virus (tobacco)	1/10	250	142
	1/100	45	11
	1/500	42	1
Arabis mosaic virus (petunia)	10^{-4}	10/10*	10/10
	10^{-5}	2/10	10/10
	10^{-6}	0/10	1/10
	10^{-7}	0/10	0/10

* Denominator is the number of *C. amaranticolor* plants inoculated and the numerator is the number of plants afterwards with systemic symptoms.

As shown, the preparations of the rod-shaped viruses were of high infectivity when prepared in borate, but of very low infectivity when prepared in phosphate. By contrast, much smaller differences were obtained with the two spherical viruses, the infectivity of arabis mosaic virus being greater from the borate preparation and that of cucumber mosaic virus being greater from the phosphate preparation.

The foregoing infectivity tests were made only on the final preparations. To determine when, during the purification process in phosphate, the loss of infectivity of the preparations of the rod-shaped viruses occurred, samples were withdrawn at various stages and tested on the leaves of *C. amaranticolor*. The three viruses reacted similarly and it was found that although the original filtrates from the leaf homogenates in phosphate or borate buffer (containing sodium EDTA and thioglycollic acid) were equally infectious, those in phosphate had lost infectivity after clarification with butanol and centrifugation, whereas those in borate had not.

Possible reasons were considered for the loss of infectivity of the three rod-shaped viruses when butanol was added to the phosphate preparations. It was thought most likely that the virus particles had become aggregated and either were lost by removal in the early centrifugation or, if retained in the supernatant, were inactivated because they were aggregated. Alternatively, it was considered that they might have been disrupted by the butanol treatment. Electron microscope examination of the final preparations of the three viruses prepared both in phosphate and in borate, however, showed that neither explanation was correct. Both types of preparation contained equivalent numbers of largely unaggregated virus particles of normal size and shape. It thus appears that, following the phosphate clarification procedure, there was no change in the gross appearance of the rod-shaped virus particles although their infectivity was destroyed. Lettuce mosaic virus prepared in phosphate was also serologically inactive against antiserum prepared from infectious (borate-prepared) virus. The reasons for these effects are being further examined.

I thank H. L. Nixon, Rothamsted Experimental Station, Herts., for making the electron microscope examinations.

Microscopic Examination of Cell Monolayers grown in Plastic Bottles

PLASTIC culture bottles composed of a non-toxic polystyrene have been shown to be superior to polyvinyl or 'Pyrex' glass bottles for estimating the radiation sensitivity of cell monolayers cultured *in vitro*[1].

During the course of investigations involving the irradiation of monkey kidney cells grown on the surface of polystyrene bottles, it was observed that exposure of the bottles to toluol caused the dissolution of the plastic, leaving the intact monolayers floating free. This suggested a method for processing and examining the free monolayers.

The cell sheet adhering to the surface of the bottle is suitably fixed. The choice of fixative is important, as some (for example, Zenker's and Helly's) cause brittleness of the cell sheet with consequent fragmentation. Of the fixatives tried, the best results were obtained with Bouin's or Susa, although methanol or ethanol fixation for 24 h at 4° C appeared to be satisfactory. Alcohol-formalin may be used provided that prolonged washing is carried out prior to staining.

After fixation, a section of the plastic, the size of a microscope slide, is cut from the bottle by means of a hot knife and processed (washing, staining, dehydration, etc.) in ordinary staining dishes. The stained sections are immersed in toluol in individual coplin jars. Within a few minutes the plastic starts to soften, and with gentle shaking the monolayer is dislodged. As it floats free it may be teased on to a glass slide and a cover-slip applied for microscopic examination.

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S W 7), at 6 p m —Mr Eric E Shipton, C B E "Patagonian Adventure" (colour films with commentary)

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (joint meeting with the SURFACE ACTIVITY GROUP, at 14 Belgrave Square, London, S W 1), at 6 p m —Dr J M Corkill "The Structure of Thin Detergent Films"

PLASTICS INSTITUTE, ENGINEERING SUB-GROUP (at "The Ring" Blackfriars Road, London, S E 1), at 6 30 p m —Mr P J Gough "Toolmaking by Spark and Electro-chemical Erosion"

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned

ASSISTANT EXPERIMENTAL OFFICER (with a degree in science, horticulture or agriculture, or equivalent) for physiological studies on vegetable crops—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (October 12)

RESEARCH FELLOW (with an M Sc or Ph D degree and/or research experience in one of the following fields neutron physics, fluctuations in electronic devices, vacuum physics and electron optics, wave optics or solid state physics including X-ray crystallography) IN THE DEPARTMENT OF PHYSICS —The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham, 4, quoting Ref 9/63/6 (October 14)

SENIOR LECTURER (with a special interest in physical-organic chemistry, preferably experience in teaching, and capable in initiating independent research) IN THE DEPARTMENT OF CHEMISTRY—Clerk to the Governing Body, Chelsea College of Science and Technology, Manresa Road, London, S W 3 (October 14)

ASSISTANT LECTURER (preferably honours graduate in zoology or physiology with suitable postgraduate experience) IN ANATOMY AND HISTOLOGY IN THE DEPARTMENT OF AGRICULTURE, Sutton Bonington, near Loughborough—The Registrar, The University, Nottingham (October 15)

READER IN BIOPHYSICS—Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, Chelsea, London, S W 3 (October 21)

STUDENT IN THE DEPARTMENT OF CHEMISTRY for research on the preparation and properties of nickel cobalt films—The Registrar, The University, Hull (October 21)

PROFESSOR OF PHILOSOPHY, PROFESSOR OF SOCIOLOGY, PROFESSOR OF PHYSICS, PROFESSOR OF CHEMISTRY, and a PROFESSOR OF MATHEMATICS—The Registrar, University of Kent, Westgate House, Canterbury, Kent (October 26)

FELLOW IN THE DEPARTMENT OF DEMOGRAPHY, Research School of Social Sciences, Institute of Advanced Studies, Australian National University—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, October 28)

CHAIR OF PURE MATHEMATICS at the University of Canterbury, New Zealand—Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1, or The Registrar, University of Canterbury, P O Box 1471, Christchurch, New Zealand (October 31)

CHAIR OF SOCIOLOGY—The Registrar (Room 22, O R B), The University, Reading (October 31)

LECTURER OR ASSISTANT LECTURER IN MATHEMATICS at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (October 31)

PLANT PHYSIOLOGIST, Principal Scientific Officer grade or Senior Principal Scientific Officer grade (active research worker with wide experience of research in plant physiology, particularly as applied to practical problems in the production of economic crops)—The Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (October 31)

SENIOR LECTURER IN THE DEPARTMENT OF PSYCHOLOGY, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Commonwealth Universities (Brance Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, October 31)

TEMPORARY RESEARCH ASSISTANT (graduate in botany, biochemistry or chemistry) IN THE DEPARTMENT OF BOTANY, to assist in aspects of amino-acid metabolism in plants being conducted by Dr L Fowden—The Secretary, University College, Gower Street, London, W C 1 (October 31)

LECTURERS (2) IN EDUCATION AT THE UNIVERSITY OF OTAGO, Dunedin, New Zealand—The Secretary, The Association of Commonwealth Universities (Brance Office), Marlborough House, Pall Mall, London, S W 1, or The Registrar, University of Otago (London and New Zealand, November 2)

Chair of Zoology—The Secretary, Queen's University, Belfast, Northern Ireland (November 30)

Research Assistant at the Radcliffe Observatory, Pretoria—The Secretary to the Radcliffe Trustees, 7 Lincoln's Inn Fields, London, W C 2 (December 1)

Animal Nutritionist (with a degree in agriculture with postgraduate training or experience in biochemistry, animal physiology or animal nutrition, or an honours science degree with postgraduate training or experience in animal husbandry, and preferably experience of nutrition work in the tropics) in the East African Agriculture and Forestry Research Organization, for investigation of metabolism of tropical and temperate type cattle with a tropical environment—The Director of Recruitment, Department of Technical Co-operation, Eland House, Stag Place, Victoria, London, S W 1, quoting Ref T/RC 264/364/02

Biochemist, Basic grade (university graduate in chemistry or biochemistry, or A R I C) in the Chemical Pathology Department, for duties which will include assays of protein bound iodine and other specialized estimations, with training in all aspects of clinical biochemistry—The Clerk to the Governors, St Bartholomew's Hospital, London, E C 1, quoting Ref No AC/321

Biologist (with postgraduate experience in microbiology) to join a group carrying out research on problems concerned with the genetics of bacteria and bacterial viruses—The Director, Medical Research Council, Microbial Genetics Research Unit, Hammersmith Hospital, Ducane Road, London, W 12

Lecturer (man or woman, with good academic qualifications and preferably some teaching experience) in Mathematics—The Principal, Avery Hill Training College, Bexley Road, Eltham, London, S E 9

Lecturer (with at least a good honours degree in chemistry, some teaching and research or industrial experience, and an active interest in research) in Inorganic Chemistry, to teach to Grad R I C , B Sc General and H N C standards—The Principal, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex

Non-Medical Biochemist (basic grade)—Dr M Lubran, Pathology Department, West Middlesex Hospital, Isleworth, Middlesex

Research Assistant (qualified for registration for Ph D degree and with a special interest in organic chemistry) in the Department of Chemistry—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W 8

Senior Technician (Grade II) (able to supervise and organize technicians and technical services) for the teaching section of the Department of Geology—The Assistant Bursar, The University, Reading

Technician or Senior Technician (female) for research work in mammalian physiology—The Administrator, University Laboratory of Physiology, Oxford

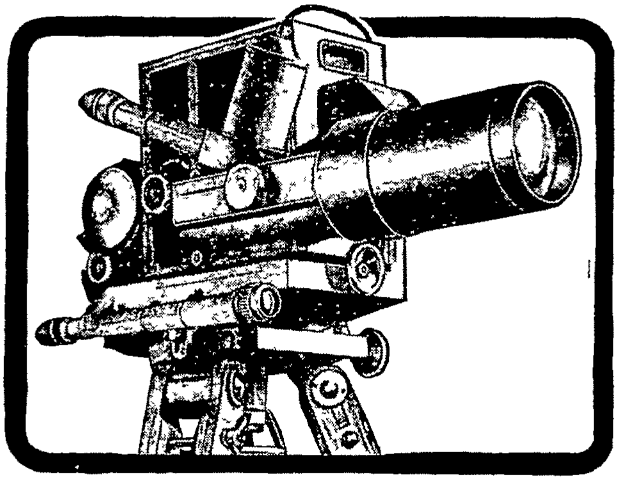
A Pentazet takes 40,000 frames a second ...by remote control!



Extreme precision at very high speed with great simplicity of operation — a Pentazet combines all three indispensable qualities for scientific work with quite unique features It is a camera perfected in Germany and designed for the whole range of scientific duties Note the special features

These features make a Pentazet unique

- Operates at speeds up to 40,000 frames a second
- Built-in heating device for exposures down to −30°C, adjustable automatically by thermo-switch
- Can be used as recording device by simple connection to cathode ray oscillograph, *records single movements of 1 millisecond and less.*
- Image lens has focal length of 45mm, relative aperture of 1:2
- Telescopic lens permits 8x magnification of normal lens image
- The lens can be focussed down to 1′8″ (0.5 metres).
- 3 pressure keys operate electric controls in compact switchboard
- Can be operated by remote control
- The camera's laterally unreversed, upright pictures can be copied without reprinting

PENTAZET

16mm and 35mm, the scientist's high-speed camera

APPOINTMENTS VACANT

SOUTH AUSTRALIAN INSTITUTE OF TECHNOLOGY

NORTH TERRACE, ADELAIDE,
SOUTH AUSTRALIA

HEAD OF DEPARTMENT OF PHYSICS

Applications are invited for the above position The salary is that of a University Reader in S A , £A3,000 by £A100 to £A3,300

Applicants should hold at least a Master's degree in Physics and should preferably have had some industrial and teaching experience

This Department, until now a part of the Mathematics and Physics Department, provides a degree course in Industrial Physics in the Faculty of Technology of the University of Adelaide It also gives service courses in Physics at various levels for other degree courses in Technology and Applied Science The Department is also responsible for a variety of subjects for Diploma and Certificate students, including Radiography, Radiotherapy and Optometry Postgraduate short courses on special topics are being developed

Subject to the general direction of the Head of the School of Applied Physics, the appointee will be required to supervise and develop the work of his Department

At the completion of six years of service, the appointee may apply for paid leave of absence for up to one year to obtain further experience abroad Other assistance may be granted at the discretion of the Council

The appointee will be eligible to join the S A Government Superannuation Fund He will be assisted in meeting reasonable travelling and removal expenses

Applications, giving personal, academic and professional details, as well as an approximate date for commencement of duty, should reach the Agent-General and Trade Commissioner for South Australia (from whom further information may be obtained) at 50 Strand, London, W C 2, not later than November 15, 1963

ROWETT RESEARCH INSTITUTE

BUCKSBURN ABERDEEN
(ANIMAL NUTRITION AND ALLIED SCIENCES)

Applications are invited for the post of Scientific Officer/Senior Scientific Officer in the Physiology Department A good honours degree in physiology or biochemistry is required An additional veterinary qualification would be an advantage, as would research experience in the field of animal metabolism A suitably qualified candidate could work for a higher degree Salary range £791 to £1,309 or £1,438 to £1,772, placing according to age, qualifications and experience F S S U superannuation Further particulars available

Apply, with fullest particulars, naming three referees, to the Secretary of the Institute, by November 1, 1963

UNIVERSITY OF ALBERTA

FACULTY OF AGRICULTURE
VACANCY
ASSISTANT PROFESSOR OF ANIMAL PHYSIOLOGY
DEPARTMENT OF ANIMAL SCIENCE

Ph D or equivalent in animal physiology, minor in biochemistry preferred Duties include fundamental and applied research with farm and laboratory animals with emphasis on environmental physiology , teaching , limited extension work Starting salary $7,500 to $9,000, depending on qualifications , to begin between January 1 and July 1, 1964

Apply, giving names and addresses of three references, to Head, Department of Animal Science, University of Alberta, Edmonton, Alberta Closing date November 30, 1963

TEA RESEARCH INSTITUTE OF CEYLON

DIRECTOR

Applications are invited for the post of Director in succession to Dr D L Gunn, C B E High academic qualifications and extensive experience of research and of the administration of research are required

The post may be filled either by direct appointment or by secondment from a research institution or university for a period of at least three, but preferably more, years

The Institute is situated at an altitude of 4,500 feet above sea level in a climate in the past found satisfactory by expatriates, including their young families, during lengthy careers with the Institute It is financed by a cess on exports of tea and has a gross annual income of about £200,000 It has ten research divisions headed by specialist officers in addition to advisory divisions The work of the Institute is of great importance to the tea industry in Ceylon and to the economy of the Island The working scientific language is English

The terms are salary scale £4,250 by £125 to £5,250 free of tax , entertainment allowance of £400 per annum , a free furnished house , free use of an official car with driver for both official and private purposes , provision exists for grants for education of children in Europe , overseas leave of six weeks annually on full pay with passages, covering also wife and up to four children , there is a district medical scheme to which the Institute is a subscriber, half of approved medical expenses of the Director and his family are paid by the Institute , contributory provident fund arrangements of 15 per cent of salary from each side, which may be used to continue existing arrangements, such as F S S U , or to make new arrangements The duration of the contract is subject to negotiation It is desired to fill the post as soon as possible

For citizens of Ceylon, India, and Pakistan, the salary scale is Rs 2,000 by Rs 75 to Rs 2,300 per mensem, plus Dearness Allowance of Rs 181 60 per mensem for a married man or Rs 139 10 for a single man Education allowance and overseas leave cannot be offered and the entertainment allowance is Rs 250 per mensem, but the other terms are the same

Formal applications in full detail, together with any specific enquiries from suitably qualified persons, should be addressed both to (a) The Chairman of the Tea Research Institute of Ceylon, "Lynwood," 50 Edinburgh Crescent, Colombo 7, Ceylon, and also (b) Dr F R Tubbs, C B E , Director, East Malling Research Station, East Malling, Maidstone, Kent, England, to arrive before November 11, 1963

Members of the Institute's Scientific Advisory Committee in the United Kingdom, i e , Mr F C Bawden, F R S , Rothamsted Experimental Station, Harpenden, Herts , Professor T A Bennet-Clark, F R S , Department of Botany, University of East Anglia, Earlham Hall, Norwich, Norfolk, Nor 05G, and Professor G E Blackman, F R S , Department of Agriculture, University of Oxford, England, may also be consulted on general aspects of the Institute and its work

SCS

Scientific Civil Service

PRINCIPAL RESEARCH FELLOWSHIPS IN GOVERNMENT ESTABLISHMENTS

To enable scientists of high calibre to undertake short-term research in the Scientific Civil Service, awards of PRINCIPAL RESEARCH FELLOWSHIPS are announced

TENURE Period of 1 year to 3 years (with possibility of extension to 5 years)
VALUE Fixed annual stipend between £1,890 to £2,640 Superannuation under F S S U

QUALIFICATIONS A candidate must produce evidence (including published work) of a considerable period of fruitful research and be accepted as a leading worker in his/her field

EXAMPLES OF POSTS

1 Royal Aircraft Establishment, Farnborough, Hants—Work in the field of ASTRONAUTICAL ENGINEERING
2 Royal Botanic Gardens, Kew—TAXONOMIST for monographic work in difficult plant groups
3 Post Office Research Station, Dollis Hill, London—Advanced developments in TELECOMMUNICATION SCIENCE

Research Fellows will be expected to propose their own fields of research

The award of SENIOR or JUNIOR RESEARCH FELLOWSHIPS will continue as heretofore

Senior Fellowship between £1,420 to £1,755 annually

Junior Fellowship between £975 to £1,310 annually

A high standard is set and candidates must hold 1st or 2nd Class Honours Degree and have completed 3 years (Senior) or 2 years (Junior) of postgraduate research

INQUIRIES to Civil Service Commission, 23 Savile Row, London, W 1, quoting S/570

AIR MINISTRY

SCIENTIFIC ADVISER

Scientific Officers/Senior Scientific Officers required in Whitehall and R A F Command H Q in the Home Counties

The SCIENTIFIC ADVISER controls OPERATIONAL RESEARCH into a wide variety of problems affecting the efficient functioning of the R A F to-day and its development to meet future demands Previous experience in operational research not essential, but flexibility and originality of mind, wide range of interests and leadership are necessary

APPLICATION FORM and booklet from Ministry of Aviation, Est 2/3 A 3, Room 516, The Adelphi John Adam Street, W C 2, quoting HC/2D/0909

D.S.I R.

GEOLOGICAL SURVEY AND MUSEUM, London

At least 2 posts, based in London, concerned with GEOPHYSICAL SURVEYS in the field Male candidates preferred The posts are graded Geologist (Scientific Officer) or Senior Geologist (Senior Scientific Officer) Good promotion prospects Non-contributory pension
At least 1st-year university qualifications in Geology and in Physics or Mathematics required Experience in Applied Geophysics an advantage

APPLICATION FORMS from Civil Service Commission, 23 Savile Row, London, W 1, quoting S/5756/63 Closing date October 18, 1963

WARREN SPRING LABORATORY, Stevenage, Herts

ASSISTANT EXPERIMENTAL OFFICER/EXPERIMENTAL OFFICER in Chemical Engineering Division for work covering wide field in chemical engineering and applied chemistry, including automatic and computer control of plant, gas-solid and gas-liquid suspensions, technology of powders and slurries, applied catalysis and surface chemistry Interest in plant as well as laboratory work required

APPLICATION FORMS from Director at above address Closing date October 15, 1963

DEPARTMENT OF AGRICULTURE AND FISHERIES FOR SCOTLAND

MARINE LABORATORY, Aberdeen

EXPERIMENTAL OFFICER/ASSISTANT EXPERIMENTAL OFFICER for STATISTICS SECTION, to assist with design analysis of experiments, analysis of statistics of commercial fisheries, production of statistical tabulations Male candidates must be prepared for periods of duty at sea Degree, including statistics with mathematics or economics, or professional qualifications in statistics plus appropriate experience essential

PARTICULARS from Establishment Officer, Room 166, St Andrew's House, Edinburgh, 1 Closing date October 15, 1963

MINISTRY OF AVIATION

EXPLOSIVES RESEARCH AND DEVELOPMENT ESTABLISHMENT, Waltham Abbey, Essex

MECHANICAL ENGINEER (graded SENIOR SCIENTIFIC OFFICER), with wide interest in physical properties of metals and non-metals, to join team studying various practical physical and mechanical engineering problems calling for novelty in approach and experimental flair Research experience in mechanical engineering or the physics of solids essential
WRITE for booklet and application form to Dr G H S Young at above address, quoting HC/2D/0923

SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

SALARIES S O £791–£1309
(Increments and special £°5 award for approved post-grad experience)
S S O £1438–£1772
(Starting salary may be above minimum)
Salaries are supplemented in the London Area

QUALIFICATIONS
S O 1st or 2nd Class Hons Degree or Dip Tech in appropriate subject Age under 29
S S O As above plus at least 3 years postgraduate research Age 26 to 31

ASST. EXPERIMENTAL OFFICER/EXPERIMENTAL OFFICER

SALARIES A E O £490 (age 18) – £691 (age 22) – £858 (age 26) – £1053
E O £1164–£1431
Salaries are supplemented in the London Area

QUALIFICATIONS
Degree, Dip Tech, H N C or equivalent in appropriate subject Under age 22, minimum qualification is 2 G C E 'A' levels in Scientific subjects A E O age 18–27 E O 26–30

Full details of careers in the SCIENTIFIC CIVIL SERVICE are available on request from Civil Service Commission, 23 Savile Row, W 1.

ORGANIC CHEMIST

Commencing salary up to £2,000 per annum with F S.S U superannuation

The Animal Health Trust require an Organic Chemist to assist the Head of the Forensic Laboratory in the direction of research and routine screening of body fluids for pharmacologically active agents

Applicants should have a good honours degree in chemistry or biochemistry with postgraduate experience in toxicological analysis and/or detoxication and show evidence of ability to direct and co-ordinate work of junior staff

Application forms from Head of Forensic Laboratory, Equine Research Station, Newmarket, West Suffolk

Closing date for receipt of applications November 18, 1963

CANADA

FISHERIES RESEARCH BOARD
PHYSIOLOGIST, ENDOCRINOLOGIST or BIOCHEMIST
$7,300 to $10,500

DUTIES. To conduct research on hormones in marine life in such a manner as to complement a continuing biochemical research programme on adrenalcortical and sex hormones in fish

QUALIFICATIONS. A Ph D degree Demonstrated research ability essential Post-doctoral or other experience in the metabolism, mode of action, or isolation and identification of steroid hormones desirable

RESEARCH ASSOCIATE
$5,200 to $8,500

DUTIES· Under the general guidance of senior scientists to assist in research related to studies on tissue culture and fish diseases

QUALIFICATIONS· Graduation from a university of recognized standing with a Bachelor's degree or better Demonstrated research ability
Each of the successful candidates will be appointed to a salary commensurate with qualifications and experience
Submit complete résumé to Director, Fisheries Research Board of Canada P O Box 429, Halifax, Nova Scotia, Canada

---

BRISTOL COLLEGE OF SCIENCE AND TECHNOLOGY
ASHLEY DOWN, BRISTOL, 7
Department of Chemistry and Biology

Applications are invited from Organic or Biochemists for appointment as

TECHNICAL ASSISTANT

to assist in research in synthetic and metabolic studies

Experience with radioactive tracers would be an advantage but not essential

Candidates should hold a good H N C or be graduates

Salary £650 per annum Superannuable post

Applications should be addressed to the Secretary and Registrar Please quote reference CST 63/70

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

Research Assistant required for work on the Cross-linking of High Polymers in solution The applicant should have an honours degree in chemistry or physical chemistry (or a good G R I C), with preferably some Research experience The successful applicant will be engaged on research sponsored by the Department of Scientific and Industrial Research Salary on appointment £825 per annum rising to £850 per annum in the second year Superannuation under F S S U

Applications, giving full details, should be addressed to Professor R H Peters, Department of Polymer and Fibre Science, the Manchester College of Science and Technology, Sackville Street, Manchester, 1, as soon as possible

Return to Research in Britain

Are you a British scientist in Canada thinking of returning to work in Britain? You may find what you are looking for, without having to go home first, in the Civil Service, the United Kingdom Atomic Energy Authority, or the Central Electricity Generating Board.

Research Fellowships and Permanent Appointments

There are openings in all branches of science. The order in which they are most numerous is (i) physics, mathematics, engineering, and metallurgy; (ii) chemistry and biochemistry; (iii) biology. The research ranges from the most fundamental to the most applied.

A selection board of scientists will be coming to Ottawa on 7th January, 1964

If you would like an appointment with them, would you write by 11th November, 1963,
to: Mr. P. C. Davidge,
Senior UKAEA Representative in Canada,
c/o Atomic Energy of Canada Ltd., Chalk River, Ontario.

An announcement to British scientists in the U.S.A. will be made in November

**Issued jointly by the Civil Service Commission,
the U.K. Atomic Energy Authority, and the Central Electricity Generating Board.**

CENTRAL ELECTRICITY GENERATING BOARD

require

SCIENTIFIC ASSISTANTS

Young men and women with an interest in experimental work are invited to apply for posts as SCIENTIFIC ASSISTANTS in the Materials Division at the Central Electricity Research Laboratories, Leatherhead, Surrey

Vacancies exist for Scientific Assistants to work under the supervision of graduate Scientists on investigations into the behaviour of special steels and ceramics at high temperatures using mechanical tests, optical and electron microscopy and X-ray techniques

Applicants should have obtained at least five G C E "O" level passes and preferably, at least two "A" level passes in science subjects

Scientific Assistants are encouraged to study for higher qualifications by part-time day release

Salaries according to age (minimum starting salary £350 per annum) with prospects of obtaining £1,080 per annum

Applications, stating age, qualifications, experience, present position and salary to N Berryman, Personnel Officer (Headquarters), 24/30, Holborn, London, E C 1, by October 14, 1963 QUOTE REF N/322

LOWER INDUS PROJECT

The team engaged on this large scale investigation and development project which covers an area of about 15 million acres is to be increased by TEN AGRICULTURAL SPECIALISTS preferably men with overseas experience in irrigated Agriculture

The new posts will be filled by men with experience in one or more of the following crop trials, reclamation of saline land trials, agricultural surveys, crop sampling surveys, economic surveys, studies into the water requirements of crop plants Project planning and feasibility assessment will be required of at least two of the appointed Specialists

All Appointments are initially for two year contracts Salaries and Allowances are negotiable and will vary with the particular specialization Free furnished accommodation will be provided in each case

Essential details only in the first instance, to The Personnel Manager, Hunting Technical Services Limited, 6 Elstree Way, Borehamwood, Hertfordshire

---

PILKINGTON BROTHERS LIMITED
Glass Manufacturers, require a

PHYSICIST

age between 25 to 30 years, at their Research Laboratories to carry out basic research work covering theoretical and experimental investigations of heat transfer and model studies of viscous and non-viscous flow in glass-making processes

The work involves design and analysis of experiments at small-scale laboratory and pilot plant level

A good honours degree in Physics is essential with some experience of university or industrial research

The salary is in a range which can rise to £2,000 per annum

Applications should be made, quoting RES/J 3, to L P Laidlaw
GROUP STAFF DEPARTMENT,
Pilkington Brothers Limited,
Grove Street, St Helens, Lancashire

APPLICATIONS ARE INVITED FOR A Post-doctoral Fellowship in haemoprotein chemistry Sound background in physical organic chemistry and/or modern analytical techniques are essential —Apply to Dr G R Schonbaum, Department of Biochemistry, University of Alberta, Edmonton, Alberta, Canada

---

Instrumentation Division Manchester

AEI

SCIENTIFIC APPARATUS SALES

AEI have a number of opportunities in the Analytical Instruments Section of their Scientific Apparatus Sales Department The Department is a rapidly expanding one, and makes a wide range of scientific equipment including mass spectrometers, X-ray spectrometers, electron microscopes, and particle accelerators

CHEMISTS An Honours graduate is required with strong interest in organic chemistry and keenness to prove himself in a new and expanding field The work involved is the introduction of mass spectrometry methods to organic chemistry groups throughout the world

TECHNICAL SALES STAFF Several Honours graduates in chemistry, physics, or other scientific discipline are required for commercial work The duties cover liaison between prospective users and AEI Application Laboratories

The preferred age limits for both appointments would be 24 to 30 Freedom to travel overseas would be essential and a foreign language would be an advantage

Please write, giving brief details of age, qualifications, experience, and present salary, and stating which type of post interests you, to

STAFF MANAGER (E25) ASSOCIATED ELECTRICAL INDUSTRIES LTD · TRAFFORD PARK · MANCHESTER, 17

BEA

RADIOLOGICAL PROTECTION

We wish to recruit two men for interesting new posts concerned with radiation protection measures for our aircraft and equipment at London Airport

SUPERVISOR

To investigate and report on radioactive contamination found and make recommendations on the protection measures necessary Applicants should have a B Sc or other appropriate professional qualification and the ability to organize and administer a monitoring and protection programme Salary range £1113 to £1308 per annum

ASSISTANT

Preferably aged 21 to 25, to record levels of contamination and generally assist the Supervisor in his duties Although a scientific background is desirable, we will consider those of high intelligence who have a keen interest in this work and the capacity for development under training Salary range £735 to £894 per annum

Apply in writing to Personnel Officer, Head Office (NA), British European Airways, Bealine House, Ruislip, Middlesex

COMMONWEALTH OF AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF PLANT INDUSTRY

FELLOWSHIP IN MOLECULAR BIOLOGY

Applications are invited for appointment to a Research Fellowship in Molecular Biology in the Division of Plant Industry, C S I R O , Canberra

The Division of Plant Industry has recently established a Unit of Molecular Biology This Unit at present consists of five scientists and is now seeking to appoint another Fellow The work presently in progress includes the study of replication and expression in RNA viruses , the evolution of enzymes and the mapping of active sites, molecular mechanisms of adaptation, of regulatory processes, and of differentiation

The Division of Plant Industry, situated in Canberra, comprises some 130 scientists conducting pure and applied research in Genetics, Plant Breeding, Biochemistry, Physiology, Microbiology, Inorganic Nutrition, Ecology, Agricultural Physics, Agronomy, and Plant Introduction

The Division is well equipped with instruments for the characterization of macromolecules, including preparative and analytical ultra-centrifuges, isotopic equipment, recording spectrophotometers, and electron microscope, and electronic computer facilities

Applicants should possess a Ph D degree in an appropriate field, or have had post-graduate research experience of equivalent standard and duration, supported by satisfactory evidence of research ability

Dependent upon qualifications and experience, appointment will be made at a salary of not less than £A1 979 per annum up to £A3,015 per annum Appointment of an applicant having outstanding qualities of leadership in research and eminence in the broad field of study would be considered up to a maximum of £A3,873 per annum Salary rates for women are £A188 per annum less than the corresponding rate for men

The Fellowship is initially for three years with the possibility of extension if mutually desired

Consideration may be given to the continuation of F S S U or, alternatively, if a secondment is arranged with the present employer, the Organization may be able to arrange to reimburse the employer's share of other superannuation schemes

Return fares paid for the appointee and his dependent family Further particulars supplied on application to
Mr P F Butler, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2,
to whom applications (quoting Appointment No 130/614) should be addressed by November 2, 1963

AUSTRALIA

If you are thinking of taking up an appointment in Australia you are cordially invited to write to us for helpful information and advice on the various aspects of Australian conditions and affairs
"Australia—A Guide for Newcomers" is one of a number of publications designed especially to help those contemplating residence in Australia, and a copy will be freely sent on request

Please write, call or telephone

UNIVERSITY OF MANCHESTER

Applications are invited for the posts of Lecturer and Assistant Lecturer in the Department of Physics in the Faculty of Science The research interests of applicants should lie in the High Energy Physics field, in which the Department has an active programme Duties to commence as soon as possible Salary scales Lecturer, £1,250 to £2,150 per annum, initial salary according to qualifications and experience , Assistant Lecturer, £1,000 to £1,150 per annum Membership of the F S S U and Children s Allowance Scheme

Applications should be sent not later than November 15, 1963, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained Applications by airmail letter in the first instance will be received from overseas candidates, who should state the names and addresses of at least three persons to whom reference can be made

---

UNIVERSITY OF EDINBURGH

DEPARTMENT OF MEDICAL PHYSICS

LECTURESHIP

Applications are invited for the post of Lecturer in the above Department Salary scale Lower £1,250 by £110 to £1,690 , Higher £1 805 by £115 to £2,150 by £110 to £2 700 per annum, with placement according to qualifications and experience, and with superannuation benefit and family allowance where applicable The successful applicant will include among his duties those of University Radiation Protection Officer and will be expected to undertake and supervise research in this and related fields The successful applicant will be expected to take up duty in October, 1963, or as soon as possible thereafter

Further particulars may be obtained from the undersigned, with whom applications (six copies), giving the names of two referees, should be lodged not later than October 12, 1963

CHARLES H STEWART,
Secretary to the University

SOUTHERN RHODESIA

MINISTRY OF AGRICULTURE

Applications invited from holders of Agricultural degrees (pass or honours) with majors in appropriate subjects Post-graduate experience a recommendation

1 POULTRY OFFICER—Matopos Research Station
Design and execution suitable research programme, including the conducting of egg-laying tests and poultry advisory work

2 AGRICULTURAL CHEMISTS—Chemistry Branch
One post Analytical Laboratory, Salisbury, concerned with analysis by chemical and spectrographic methods, agricultural products and materials Duties analytical and advisory
The other post Soil Survey Section , soil surveys for Land Settlement, Irrigation and other schemes Staff usually spend winter months in the field and for the remainder of the year are occupied in the Salisbury offices and laboratories on analysis of the samples collected and compilation of maps and reports

3 SEED RESEARCH OFFICER, SALISBURY
Applicants should have an honours degree in either Plant Pathology or Microbiology Duties include investigation of seed-borne diseases, detection and control, and various aspects of seed physiology

4 ANIMAL HUSBANDRY OFFICER—Matopos Research Station
Applicants should possess Degree with Animal Husbandry major subject A diploma in sheep and wool a recommendation Duties include physiological and nutritional studies on exotic and indigenous beef breeds and assisting in all matters pertaining to beef production in the lower rainfall areas of Southern Rhodesia

Salaries are in the Professional Officer scale £900 by £100 to £1,200 by £75 to £1,350 by £60 to £1,770 by £65 to £1,900 per annum

Entry point depends on qualifications and experience

Pension Benefits—Good leave conditions—Low Income Tax—Good sporting facilities—Attractive climate—*Fares Paid*

Applications to and further details from Secretary (R), Rhodesia House, 429 Strand, London, W C 2

Closing date October 16, 1963

GOVERNMENT OF UGANDA

VACANCY FOR A BIOCHEMIST

The Department of Technical Co-operation invites applications for the post of Biochemist, Uganda Duties To work with other members of the research staff in establishing modern biochemical techniques for research into adaptation and diseases of domestic livestock in Uganda The programme is concerned principally with the study of serum proteins in relation to immunity to tropical animal diseases and the estimation of drug levels in the animal body Qualifications Candidates must possess a first- or second-class honours degree in chemistry, or veterinary qualifications with additional specialization in biochemistry Experience of the application of modern bio-chemical techniques to the study of animal diseases desirable but not essential Terms Appointments on contract for one tour of 21 to 27 months in the salary scale £1,266 to £2,448 a year Gratuity (taxable) of 25 per cent of emoluments on satisfactory completion of contract Initial salary according to experience Government quarters usually available at a low rental Free passages for officer, wife and dependent children Education allowances Generous leave

Applicants should normally be nationals of the United Kingdom and Great Britain Apply to the Director of Recruitment, Department of Technical Co-operation, Eland House, Stag Place, Victoria, London, S W 1, stating full name and giving brief particulars of qualifications and experience quoting RC 217/153/04/C1

UNIVERSITY OF LONDON

CHAIR OF MEDICAL MICROBIOLOGY AT ST THOMAS'S HOSPITAL MEDICAL SCHOOL

The Senate invite applications for the Chair of Medical Microbiology tenable at St Thomas's Hospital Medical School (salary in the range £3,645 to £4,445 a year)

Applications (ten copies), must be received not later than November 20, 1963, by the Academic Registrar, University of London, Senate House, W C 1, from whom further particulars may be obtained

ROYAL PERTH HOSPITAL

WESTERN AUSTRALIA

HOSPITAL MICROBIOLOGIST

Applications for the above post are invited from medical graduates with suitable experience in Microbiology The Hospital Department of Microbiology is under the control of the Director of Hospital and University Services in Microbiology

The successful candidate will be required to assist the Director (Professor N F Stanley) in the administration of the routine laboratory and clinical services of the Hospital Department of Microbiology, to act in the absence of the Director and to carry out special investigations from time to time

Royal Perth Hospital is the main teaching hospital of the Medical School of the University of Western Australia The Hospital Department of Microbiology is well equipped, adequately staffed for the performance of all modern microbiological techniques, functions in close association with the University Department of Microbiology in the adjacent School of Medicine and the Virus Research and Diagnostic Laboratory of the Department of Public Health

SALARY Within the range of £A3,800 to £A4,350 per annum, commencing rate according to qualifications and experience Salary will commence from the date the appointee takes up duty

CONDITIONS OF SERVICE Include annual leave, long service leave (three months on full pay after each seven years service) and sick leave Study leave may be granted as a privilege for some special purpose approved by the Board Contribution to the State Superannuation Scheme is required, or alternatively, the Hospital would consider subsidizing the appointed officer's existing commitments under an approved scheme or endowment policy

TRANSPORT EXPENSES A travel grant equivalent to minimum First Class sea passage will be provided for successful applicant and family (under 16 years of age), together with an allowance of £S200 for the cost of removal of personal effects, etc (excluding furniture and motor vehicle), subject to a bond to remain in the Hospital's service for a minimum period of three years

A memorandum of Information including further details of the Department of Microbiology is available upon request

Further information concerning Royal Perth Hospital and the State of Western Australia may be obtained from the Agent General for Western Australia, Savoy House, 115 Strand, London, W C 2

Applications in writing should include date of birth, qualifications, experience, present and previous appointments, a list of publications, a recent photograph and the names and addresses of three referees

CLOSING DATE November 30, 1963

Joseph Griffith,
ADMINISTRATOR

AUSTRALIAN NATIONAL UNIVERSITY

SENIOR LECTURER IN PHYSICS OR THEORETICAL PHYSICS

Applications are invited for appointment to the new post of Senior Lecturer in Physics or Theoretical Physics in the School of General Studies of the University The appointee will be required to take up duty on January 1, 1964, or as soon thereafter as possible Applicants should hold the degree of Doctor of Philosophy in Physics or equivalent qualification Some teaching experience is desirable but not essential Research interests in the Departments of Physics and Theoretical Physics are in the fields of atomic collision processes, atomic diffusion in metals, the design and use of shock tubes, and theoretical physics The salary range for a senior lecturer is at present £A2,450 by £A110 to £A3,000 per annum Commencing salary will be [illegible] accordance with qualifications and experience [illegible] are at present under review [illegible] formation and the forms which [illegible] an application may be ob- [illegible] cretary Association of Com- [illegible] es (Branch Office) Marl- [illegible] Mall, London, S W 1 Ap- [illegible] ndon and Australia on [illegible]

[illegible] COUNCIL REQUIRE [illegible] preferably not under [illegible] technical aspects of [illegible] and equipment, for [illegible] Colindale Avenue, [illegible] ale rising to £1,281 [illegible] provision —Written [illegible] fessional referees), [illegible] ting ref E10/29

GHANA ACADEMY OF SCIENCES

Applications are invited for the following vacancies in the Cocoa Research Institute, Tafo

Secretary Duties Applicant to be responsible to the Director for the general administration of the Institute, knowledge of accounting will be an advantage Qualifications Applicants, who must be between the age of 20 to 45, should hold a degree of the A C I S or the A C C S Salary in range £1,050 to £1,900 per annum

Entomologist Duties Responsible for research work on insect pests of cocoa Qualifications Good honours degree or higher degree in zoology with postgraduate experience in entomology Salary To be determined according to qualification and experience is in the range £1 050 to £2,300 per annum (for Ghanaians) and £1,260 to £2,750 per annum (for expatriates)

Spectrographer Duties To include running and maintenance of a spectrographic laboratory concerned with mineral analyses of plants and soils Qualifications A good honours or higher degree in physics or chemistry with postgraduate experience in the running and maintenance of a spectrographic laboratory concerned with mineral analyses of plants and soils Experience in handling and measuring radioisotopes would be an additional advantage Salary To be determined according to qualifications and experience is in the range £1,050 to £2,300 per annum (for Ghanaians) and £1,260 to £2,750 per annum (for expatriates)

Appointments are on contract terms for a period of four tours each of 15 to 18 months' duration including leave For Ghanaians appointment will be for five years in the first instance, including two months leave in each calendar year Staff Provident Fund Scheme facilities available.

For further information and application forms, please write, stating the post in which you are interested to the Director of Recruitment, Ghana High Commission, 248 Tottenham Court Road, London, W 1

ROYAL COLLEGE OF ADVANCED TECHNOLOGY

SALFORD

DEPARTMENT OF MECHANICAL ENGINEERING

RESEARCH STUDENTSHIPS

Applications are invited for a number of Research Studentships Applicants should have a good degree or Diploma in Technology in Mechanical Engineering or in an applied science Applicants with alternative qualifications of high standard may also be considered Each person appointed will join one of the research groups in the Department and will carry out research for a higher degree or for either Membership of the College of Technologists (M C T) or the Fellowship of this College There are new and well-equipped laboratories and good workshop facilities available The Studentships are renewable annually up to a maximum of three years and carry an annual grant of £500 to £900 The commencing point may be above the minimum Additional income of up to £100 per annum may be derived from carrying out demonstrating work in the Department

Further particulars may be obtained from the Secretary, Royal College of Advanced Technology, Salford 5, Lancs, to whom applications should be submitted by October 31, 1963, quoting reference ME/55

UNIVERSITY OF ADELAIDE

CHAIR OF INORGANIC CHEMISTRY

Potential applicants for the Chair, for which applications were invited by advertisement last month, are notified that the

CLOSING DATE FOR APPLICATIONS HAS BEEN POSTPONED

until October 30, 1963

Full particulars may be obtained from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1, or from the Registrar of the University

Applications (in duplicate), should reach the Registrar of the University not later than October 30, 1963

UNIVERSITY OF MELBOURNE

DEPARTMENT OF STATISTICS

Applications are invited for a position of Senior Lecturer in Statistics The salary range is £A2,450 to £A3 000 per annum Initial salary will be determined according to qualifications and experience Superannuation similar to F S S U in Great Britain will be provided

Conditions of appointment may be obtained from the Secretary Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close in Australia and London on November 30, 1963

COMMONWEALTH AGRICULTURAL BUREAUX

Applications are invited for the post of Director, Commonwealth Mycological Institute, Kew, England The requirements are a wide knowledge of plant pathology (particularly of tropical crops) and experience in research in the subject, administrative ability and experience, literary taste, and some knowledge of languages Familiarity with systematic mycology and identification work is essential, and acquaintance with medical and veterinary mycology and scientific publication processes are also desirable Salary scale £3,150 to £3,212 10s to £3,275, plus £60 London weighting at each point, with provision for superannuation

Applications should be submitted by December 31, 1963, to the Director, Commonwealth Mycological Institute, Ferry Lane, Kew, Surrey, England, from whom full particulars, including regulations regarding provision of passages to overseas candidates on first appointment can be obtained

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

(Faculty of Technology in the University of Manchester)

Applications are invited for the post of Special Research Assistant to work with a research team engaged on synthetic aromatic organic chemistry The research and development work involved is particularly interesting and requires practical skill and ability, combined with a sound working knowledge of organic chemistry It is not intended that the successful applicant should be registered as a research student Salary according to qualifications, in the range £880 to £1,200

Application forms may be obtained from the Registrar of the College, Sackville Street, Manchester, 1, within ten days of this advertisement.

UNIVERSITY OF THE WEST INDIES

Applications are invited for (a) Lectureship or (b) Assistant Lectureship in Agricultural Economics at St Augustine, Trinidad, from graduates with honours degree in economics and postgraduate specialization in agriculture or agricultural economics, or honours degree in agriculture or agricultural economics and postgraduate specialization in agricultural economics Some knowledge of tropical and West Indian agriculture desirable but not essential Preference given to candidates with interest or experience in production economics Duties include assisting in teaching economic principles and their application to agriculture to undergraduates and postgraduates Salary scales (a) £1,300 by £60 to £1,660 by £80 to £2,100 per annum (b) £1,050 by £50 to £1,200 per annum Child allowance £150 per annum first child, £100 per annum second, £50 per annum third F S S U Housing allowance of 10 per cent of salary, or, if available, unfurnished accommodation will be let by University at 10 per cent of salary Up to five full passages on appointment, on normal termination and on triennial study leave

Detailed applications (six copies), naming three referees, by October 28, 1963, by persons living in the Americas and the Caribbean area to Registrar, University of the West Indies, Kingston, 7, Jamaica, and by all other persons to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London W C 1 Further particulars may be obtained similarly

RHODES UNIVERSITY

GRAHAMSTOWN

Applications are invited for the post of Lecturer in Entomology from January, 1964 The salary scale is £1,170 by £60 to £1,650 per annum A vacation savings bonus, according to Public Service Regulations, is also payable Previous experience and qualifications may be taken into consideration in determining the commencing salary The salary scale given above is under review and it is hoped that it may be possible to introduce an improved scale in 1964

Full particulars and application forms may be obtained from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close in South Africa and London on October 31, 1963

SPILLERS LIMITED REQUIRE A YOUNG graduate, to run extensive experiments on chicken and turkeys—the post may suit an agriculture graduate wanting to enter this field The post will be permanent and superannuated, and a profit sharing scheme is in action Salary according to training and experience —Apply to Dr M J Head, Spillers Limited, Animal Nutrition Research Laboratory, Middle Aston House, Nr. Steeple Aston, Oxford

CALLING GRADUATES OVERSEAS

Do you like the idea of working in an international and expanding research organization which provides a real challenge in a wide range of fields ? Unilever Research in the United Kingdom has vacancies in its four Research Departments for physical and organic chemists, physicists and biochemists. If this appeals to you, come and meet the Staff Officer of the U K laboratories who will be visiting the U S.A and Canada in November of this year

Please write for an appointment or for further information to:

Dr. A. CROSSLEY,

Unilever House, Blackfriars,
London, E.C.4, England.

(SECOND ADVERTISEMENT)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF ZOOLOGY

Research Assistant, with experience in Embryology and/or Biophysics, is required by the Department of Zoology for work on the effect of drugs on the uptake and distribution of water in the developing embryo The appointment will be for three years in the first instance Salary within the range of £1,000 to £1,150 per annum, plus F S S U

Applications (three copies), with curriculum vitae and the names of two referees, should be sent to Dr P H Tuft, Department of Zoology, University of Edinburgh, West Mains Road, Edinburgh, not later than October 31, 1963

CHARLES H STEWART,
Secretary to the University

ROTHMANS FELLOWSHIPS

Applications are invited for Rothmans Fellowships which are awarded under the Rothmans University Endowment Fund set up by Rothmans of Pall Mall (Australia) Limited to enable Fellows to undertake postgraduate work within a university or approved institution The Fellowships will be awarded at two levels The Senior Fellowship is of an annual value of not more than £A4,000 The Junior Fellowship is in two grades, the first of an annual value of from £A1,000 to £A1,250, the second of an annual value of not more than £A2,300 A Fellow may be paid travelling expenses incurred in taking up the Fellowship and returning to his home In addition, an amount of £A500 per annum towards fees and expenses including the purchase and maintenance of equipment may be paid to the University or institution where the Fellow is working Preference in the award of the Fellowships will be given to those applicants who wish to work in an Australian university or institution and only in exceptional circumstances will an award be made in respect of work to be done elsewhere Applicants must have had at least one year's postgraduate research experience

Application forms and further details may be obtained from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close on November 30, 1963, with H McCredie, Secretary, Rothmans University Endowment Fund

achievement.

Technical genius, organised ideas and practical experience have been combined to make the TECAM(R) Micro-tensile Testing Machine the only instrument in the world capable of measuring forces of between 1 milligram and 400 grams and extensions from a few Ångstroms to 15 millimetres without drift

With a repeatability better than 10^{-6} millimetres and without bolting it to virgin rock this beautiful instrument brings new possibilities into "whisker" work Write or phone for full details

ICN MIMICS EFFECTS OF THYROXINE ON ISOLATED LIVER MITOCHONDRIA

Cyanogen Iodide (ICN) has been found to mimic in most respects Thyroxine's effects on isolated liver mitochondria (¹) It is stable in water and serves as a donor of I+

ICN behaves like Thyroxine in these respects

1 A quantity as small as 10^{-6}M produces substantial water uptake and swelling in rat liver mitochondria As with Thyroxine, ICN produced swelling is inhibited by serum albumin and strong sucrose (0 75M)

2 Antimycin A, Amytal and Cyanide also inhibit ICN produced swelling Thyroxine has been reported to display similar properties (² ³)

3 EDTA is effective against ICN produced swelling It is also effective against thyroxine (⁴)

4 ATP causes rapid shrinking of ICN swollen mitochondria It behaves exactly the same with Thyroxine caused swelling (⁵)

UNIQUE HYPOGLYCEMIC AGENT FOUND FOUR TIMES AS POTENT AS TOLBUTAMIDE

4 Dimethyl Amino N Methyl 2, 2 Diphenyl Valeramide HCl was recently reported to be four times as potent as tolbutamide in lowering blood sugars

It appears to act through a different mechanism than hypoglycemic agents which increase the oxidation of glucose

Dulin et al conclude that 4 D M D V appears to act by inhibiting liver glucose output—not by glucose oxidation or inhibition of metabolic effect of adrenal hormones (¹)

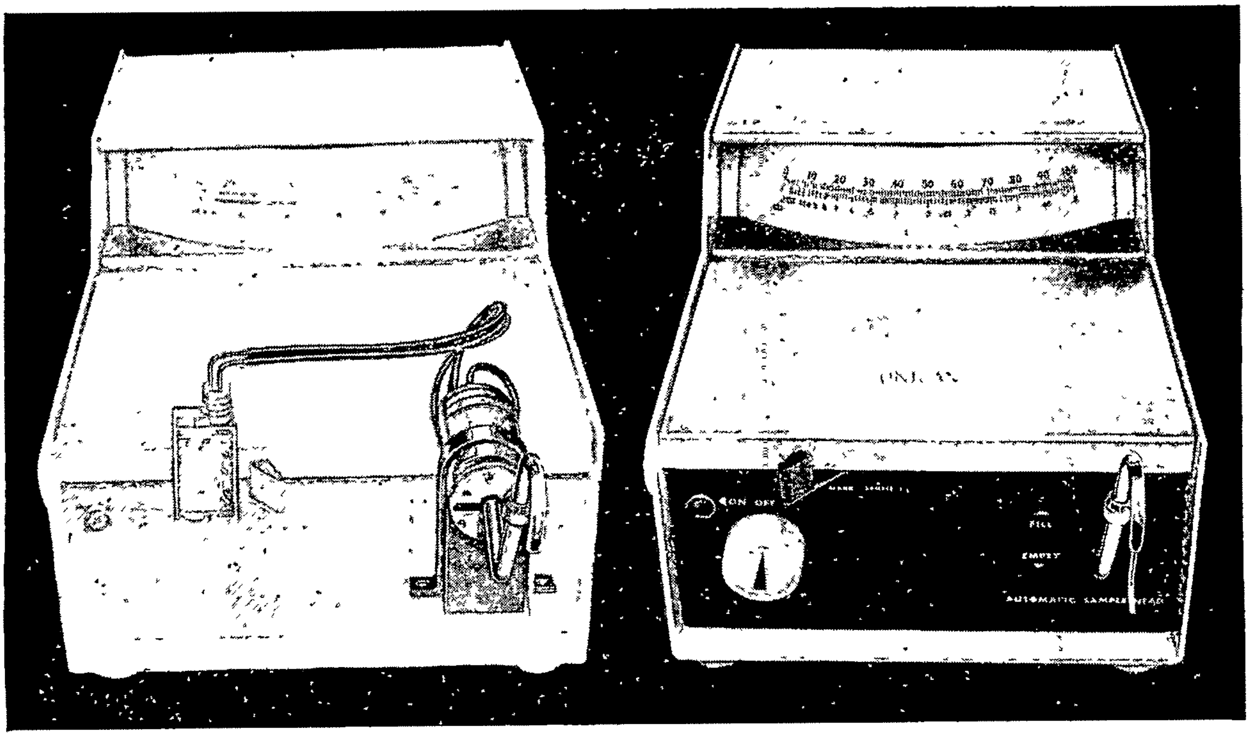
FASTER, EASIER COLORIMETRY



WITH THE NEW UNICAM AUTOCELL COLORIMETER

The new Unicam Autocell Accessory dispenses with the time-consuming and tedious repetition involved in filling, emptying and cleaning cells Risks of contamination and breakage are reduced to a minimum and the Autocell provides further advantages in improved accuracy and greatly increased speed. Designed and engineered for maximum convenience and performance, the SP 1300 Autocell Colorimeter has a corrosion-resistant stainless steel sample compartment which can be dismantled in seconds for easy cleaning. The instant-selection filter disc is also easily removed for cleaning or for the interchange of filters. A high-sensitivity galvanometer together with a long scale produces a high order of accuracy. Write for further details of this outstanding instrument or for a sample method sheet.

Clinical Methods

Delivered with every SP 1300 is an indexed manual containing operating instructions and a set of 16 Clinical Method Sheets giving instructions for the completion of the most commonly occurring colorimetric determinations for pathologists, biochemists and medical laboratories generally. Other series are shortly to be prepared.

1 Determination of urea in blood
2 Determination of uric acid in blood
3 Determination of glucose in blood
4 Determination of haemoglobin in blood
5 Determination of bilirubin in plasma
6 Determination of total cholesterol in serum or plasma
7 Determination of creatinine in plasma and urine
8 Determination of total protein in plasma
9 Determination of inorganic phosphates in plasma and whole blood
10 Determination of alkaline phosphatase in serum or plasma
11 Determination of acid phosphatase in serum or plasma
12 Determination of amylase in plasma
13 Determination of salicylates in plasma, serum, C S F, urine, etc
14 Determination of glutamic-oxalo-acetic and glutamic-pyruvic transaminases in serum
15 Determination of urea and ammonia in urine
16 Determination of 17-ketosteroids and 17-hydroxycorticosteroids in urine

A MODEL FOR TECHNICAL ASSISTANCE

MR J G HARRAR'S review, as president of the Rockefeller Foundation, in the annual report of the Foundation, 1962*, is of special interest both for its survey of the philosophy that has guided the Foundation during the fifty years of activity which were completed in the spring of 1963 and its attempt to assess the function of the Foundation in the years ahead This survey of its activities during the past half-century directs attention to the Foundation's efforts in advancing human knowledge and its application year by year to those ills and problems which limit the freedom and satisfactions of mankind Mr Harrar shows clearly how the Foundation's early efforts to deal with problems of public health on an international scale led first to programmes for developing schools of public health, to training a growing body of physicians, nurses and technicians to practise in this field, and then to a more general entry into the field of medical education

Even at this stage of his retrospect, it is apparent that the Rockefeller Foundation has set a pattern on which, a generation or more later, the soundest efforts in the field of technical assistance have been modelled This is no less true of its work in other fields, such as the national sciences or the social sciences, both of which the Foundation created Divisions in 1928 In this context the programme for the agricultural sciences which arose in 1943 out of the Foundation's increasing concern with human nutrition and food production gains special interest The story of the correction in the past twenty years of the deficient position of Mexico with respect to its basic foods is not only fascinating in itself, but also of profound significance in relation to the problem of feeding the world's expanding population to-day It corroborates all that Prof. Martin Jones said at Aberdeen on August 30, in his address to Section M (Agriculture) of the British Association, on the need to help and educate the peoples in every country to develop their own resources for the production of their basic needs for food

In 1929 the Rockefeller Foundation also established a Division of Humanities, the programme for which included the study of history as important for background and perspective in contemporary thinking and in interpreting change and continuities in the world to-day it was one of the first to introduce reforms in serving the needs of library development From all these activities the Foundation has drawn a rich body of experience as a basis for judgments on the lines of future policy Much of this experience is highly significant for others who are concerned with technical co-operation in the developing nations, and it is notable that the careful and intensive examination of this experience by the Foundation which has marked the year 1962 has led the Foundation to decide to place increasing emphasis on the ecological approach to human problems

This, in Mr Harrar's judgment, is the fundamental decision taken during the year, and it is in line with a marked emphasis on the same ecological approach which characterized discussions at the recent meeting of the British Association at Aberdeen The note was struck by Sir Eric Ashby in respect of higher education in his presidential address It was implicit in that on land use in the Scottish uplands in joint sessions between the Sections for Agriculture, Geography, Botany and Forestry, as well as in others arranged by Section N (Sociology) and on planning jointly between Section F (Economics) and Section X (General) Moreover, in Section D (Zoology), Dr F Fraser Darling's presidential address on the unity of ecology was followed by a joint discussion of the subject with Section K (Botany)

The concept that a given society, whatever its stage of development, stands in intimate relation with all aspects of its environment and that a change in one necessarily affects the others now commands wide acceptance outside the political world Even there the Beeching proposals and the reaction to them have forced the politician to recognize the value of an ecological approach, which can sometimes assist advance simultaneously on several fronts and avoid some of the internal torques and tensions induced by rapid development in one sector and slow advance in others Without such an approach, there may be little hope of meeting successfully the immeasurably greater challenges of to-day and the future While it could scarcely be said that in discussing British national parks in his presidential address to Section E (Geography) at the Aberdeen meeting, Prof H C Darby was concerned with ecology, the experience with national parks in Britain is, in fact, as emphatic a demonstration of the need for an ecological approach to some problems as is the experience and functioning of the Nature reserves themselves

The process of consolidation which the Rockefeller Foundation began in 1962 does not substantially change its pattern of operation, though it brings together in a more precisely focused effort activities which were hitherto separate Nor does it affect the abiding conclusion, drawn from the Foundation's experience and which Mr Harrar reiterates in this review, that the best investment a private philanthropy can make is in the development of the talented and promising individual within an area of opportunity Essentially all the progress in which the Foundation can claim to have had some role has derived from the energy, ability and dedication of those who have been assisted through contributions to their training or professional activity Now through this policy there has been created throughout much of the world a corps of competent individuals who can begin to take increasing responsibility for building up local projects and institutions

Mr Harrar does not suggest that help from the Rockefeller Foundation has been other than modest in proportion to the total needed, but the objective in each instance has been to provide support at critical moments and in such a manner as to assume maximum leverage towards progress Hope for the future, he believes depends on success in achieving educational and professional opportunities for an ever-increasing number of men and women with the intellectual capacity and motivation to contribute to social progress To this end the Foundation expects to continue its programme of fellowships, scholarships and study awards, to assist the intellectual development and learning of individuals, under which more than 16,000 scientists and scholars have already benefited At the same time, the pattern of the training awards will be integrated with other types of work in an over-all ecological approach

---

* The Rockefeller Foundation President's Review, 1962 Pp v+87 (New York The Rockefeller Foundation, 1962) See also p 121 of this issue of *Nature*

To-day Mr Harrar believes the training process has been carried to a point at which it is readily possible to identify opportunities for concentration A half-century of effort in many areas by the Foundation and other agencies has now trained individuals over a wide spectrum of needed skills to staff national institutions and programmes As emerging indigenous institutions accept increasing responsibility for training their nationals, outside aid can be concentrated on selected institutions rather than on individuals, to help build them into positions of excellence and permanence in which they can satisfy ever larger proportions of the national educational needs and aims Ultimately, some of these institutions can be expected to extend their influence beyond national boundaries to become regional centres

Mr Harrar does not discuss the political presuppositions of stability and order implicit in such a policy, but, in the climate of to-day, this policy is clearly wise In accordance with it, the Foundation decided in 1962 to centre its concern for institutional development primarily on selected universities in the less-developed countries By thus narrowing its objectives and utilizing an ecological approach for its attainment, the Rockefeller Foundation believes it can promote a better relation between the universities and their environments In many less-developed countries there is, for example, a serious lack of balance between the ability of the institutions to serve society and the demands made on them to produce the trained and competent specialists required in a host of fields.

This lack of balance may be due to various causes Sometimes it is simply one of size the universities have neither the student capacity nor the staff to handle the training of the necessary personnel Elsewhere it may be due to the tardiness of the universities, often among the most conservative institutions in the social structure, to adapt the courses they offer to the manifold kinds of skills and competence demanded by complex societies Yet again, relatively sudden influxes of large numbers of students have so diluted the authority of the university and academic quality that the very purpose and function of the university have been weakened

The Rockefeller Foundation fully recognizes that these different situations require handling in different ways, nor does it contemplate any attempt to transplant the American system Quite apart from the increasing extent to which the Governments of the developing countries now recognize the importance of bringing their university systems into consonance with present-day requirements, the form which any satisfactory system takes must develop from within the universities themselves and from the societies which support them What the Rockefeller Foundation seeks to do is rather to assist those centres of higher education which are already emerging as models which others can emulate, and, by thus building on established points of strength, help to raise the level and tone of the institution as a whole

This new policy is as firmly in line with the basic objectives of the Foundation as the philosophy behind it is in harmony with that which inspired the concentration on investment in the development of the talented and promising individual All nations need the strength which comes from stable institutions of higher learning to serve the intellectual and other needs of the population, and where such institutions do not provide a growing body of alumni contributing uniquely to national economic and social stability, democratic institutions are unlikely to function Further, without in any way repudiating the principle of the international interchange of scientists and scholars, which is always rewarding, the Foundation is now dedicated to the principle that a gradual, steady shift to education at home is the solution towards which the developing countries should progress

Besides this establishment of a limited partnership with several universities aimed at overall development of the university pattern and process, the Rockefeller Foundation had, even earlier than 1962, fostered the establishment of an international research institute working to increase production of a vitally needed food in a highly important part of the world The International Rice Research Institute is part of this programme of institutional development and is expected also to contribute to the development of a university and ultimately to become part of it Support for this programme will be given both directly through the reinforcement of faculty, provision of equipment and library materials and, indirectly, through training awards for junior faculty and the support of visiting specialists In so far as it is able, the Foundation will seek to promote a balanced university development, aiding the whole university and not selected departments or schools separately

It is obvious that the re-orientation of the work of the Rockefeller Foundation is of profound significance for those concerned with technical assistance generally, and this latest report is one that will doubtless be closely studied by the Secretary for Technical Co-operation, Mr Robert Carr Moreover, not only does the experience of the Foundation bear closely on the problems that Britain is now encountering in expanding her educational assistance overseas but also it is relevant in the field of research It should not be overlooked that this record of half-a-century's effort deals with the closure of projects and transfer of staff to new areas. It is not simply a record of new ventures, and Mr Carr might well ponder the implications of this record for Britain's own overseas research effort for which his Department is now responsible, though so far silent

What stands out above all from this record is the imagination and insight with which the private institution has used its opportunities and the high sense of responsibility with which it has formulated and executed its programmes While a private foundation cannot command the resources which are at the disposal of a Government, it is sometimes free from the limitations which are inevitable in Government effort and especially in dealing with other countries Whatever the difference in the extent of resources and in the manner in which programmes are executed, the objectives of Government policy and of Foundation policy can well be identical The improvement of the communication of knowledge and its application, the infusing of cultural and moral values much more pervasively through the intricate fabric of contemporary society, the encouragement of creative activity, whether by assisting the talented and promising individual, or by helping the development of new patterns and institutions which will sustain such work—these are no monopoly of the Rockefeller Foundation or any other private institution The latest review by the president of the Foundation is especially a challenge to Britain to match the new opportunities which confront her in this changing world with vision and resource and generosity not inferior to those which in former generations were brought to the service of Empire and Commonwealth

CHEMISTRY AND THE DEVELOPMENT OF MEDICINE

Chemistry in the Service of Medicine

Edited by F N L. Poynter Pp 207 (London Pitman Medical Publishing Co , Ltd , 1963) 25*s*.

THIS book, *Chemistry in the Service of Medicine*, consists of twelve papers, which were read at the second British Congress on the History of Medicine and Pharmacy, organized by the Faculty of the History of Medicine and Pharmacy of the Worshipful Society of Apothecaries, and held in London during September 1961 These papers are authoritative historical reviews and complement each other, hence a clear picture is thereby obtained of a rapidly developing situation in which both chemistry and medicine stimulate each other and profit by each other's advances Many of the distinguished contributors have made significant advances in their respective fields, such now being the subject of historical review It is amply demonstrated in this publication that history is not simply a record of things of the past but intimately connected with the present which it helps to shape

The objectives of the Congress are carefully explained by Dr W S C Copeman, chairman of the Faculty, in a short preface The introduction is by Sir Alexander (now Lord) Todd, who traces the growth of the relationship of science, in particular chemistry, in the development of medicine He points out that medicine did not really begin to develop to any great extent until there had been a rapid expansion in our knowledge of the basic sciences He speculates as to the future developments in the inter-relationships of medicine and the basic sciences

The first paper, by Dr A G Debus, is entitled "Paracelsian Doctrine in English Medicine", and the second, by Dr F W Gibbs, "Boerhaave and the Place of Chemistry in Medicine". Both these papers deal with the early history of medicine The third paper, by Prof D McKie, is entitled "Chemistry in the Service of Medicine 1660–1800" In this, the growth of chemistry during the period is described It is shown that during this period chemistry invaded the territory of physiology and entered the service of medicine but as an independent subject The fourth paper is by Prof F G Young and is entitled "The Rise of Biochemistry between 1800 and 1900" The development of biochemistry during this period is described, but it is pointed out that although there were many distinguished British chemists, they took little or no interest in the application of their chemical knowledge to the solution of biological problems, which was in markedc ontrast to many of their illustrious Continental colleagues This state of affairs is discussed in relation to the educational system then existing in Britain Reference is also made to the lack of encouragement given to the late Sir Frederick Gowland Hopkins when he expressed his intention to apply chemistry to the study of biological processes

The fifth paper, by Prof W D M Paton, is entitled "The Early Days of Pharmacology" The distinction between *materia medica*, therapeutics and pharmacology is explained and the development of the subject from the beginning of the nineteenth century is reviewed, but Prof Paton estimates that the subject has shown its greatest degree of expansion during and following the period 1930–40 The inter-relationships existing between chemistry and pharmacology with regard to their respective advances are discussed In the sixth paper, Dr W D Foster traces the development of chemical pathology from its beginnings in the seventeenth century until its establishment as an essential part of modern medicine about the year 1925 Dr Foster quotes an authority, who, in 1924, stated that the use of chemical pathology in clinical medicine was limited to the investigation of glycosuria, renal disease and disturbances associated with acid-base balance The seventh paper is by Sir Charles Dodds and is entitled "Chemistry and Endocrinology" The historical development of endocrinology in relation to chemistry is described Considering the multitude of chemical compounds produced by such an organ as the adrenal gland, Sir Charles Dodds suggests that chemistry owes a considerable debt to medicine and in particular to endocrinology The eighth paper, entitled "The Contribution of Chemistry to Cancer Research", is by Prof A Haddow Prof Haddow considers that the main contribution of chemistry to cancer research is along fundamental lines Chemical constitution and carcinogenesis are discussed.

The ninth paper is by Dr T F Macrae and is entitled "Chemistry and Nutrition" The development of our knowledge concerning the availability of food, food additives, vitamins, proteins, carbohydrates and fats is discussed The tenth paper is entitled "Chemistry and Genetics" and is by Prof D G Catcheside, who discusses the development of the subject Prof Catcheside points out that the history of the advances in the chemistry of genetics has been largely influenced by the rapprochement between genetics and biochemistry Recent advances owe much to the newer techniques of chromatography, electrophoresis and the use of isotopes The eleventh paper, entitled "From Antiseptics to Antibiotics", is by Dr W A R Thomson, who concludes his paper by suggesting that a careful co-ordination of the two complementary methods of attack on micro-organisms—antibiotics and immuno-therapy—is necessary The twelfth and final paper is entitled "Origin and Rise of Synthetic Drugs" and is by Dr F L Rose Drugs used in the treatment of malaria and sleeping sickness and the sulphonamide drugs are some of the subjects discussed Reference is also made to the use of organic substances capable of producing a colorimetric reaction in the study of the fine detail of cell structure

Most of the papers are followed by a list of references of great historical significance S L TOMPSETT

HIGH-ENERGY PHYSICS

Proceedings of the 1962 International Conference on High-Energy Physics

At CERN, Geneva, 4th–11th July 1962 Edited by J Prentki (Sponsored by the International Union of Pure and Applied Physics) Pp xxiv + 950 + 2 plates (Geneva CERN—European Organization for Nuclear Research 1962) 60 Swiss francs

THE first seven pioneering conferences on "High-energy Physics" were held annually during 1951–57 at the University of Rochester Since 1958, however, the conferences have been sponsored by the Commission on High-energy Physics of the International Union of Pure and Applied Physics and the successive annual conferences have been held at CERN, Kiev and Rochester The conferences are now to be held biennially, and the 1962 conference was held during July 4–11 at CERN. The *Proceedings* have now been published and consist of a large volume of 950 pages, recording the substance of 208 papers presented to the conference together with the discussions on them, which were organized in twenty parallel, one special and thirteen plenary sessions There are 810 illustrations and drawings, including two colour plates The papers recorded represent only a selection of the total number presented to the conference, and in order to speed up the process of publication the editing and checking were reduced to a minimum It is with considerable pride that the Scientific Information Service of CERN, which was responsible for the publication, was able to announce the publication of the *Proceedings* in record time on October 25, just fifteen weeks after the conclusion of the conference

The *Proceedings* follow the general plan of the conference, which was divided effectively into two parts. The first three days, July 4–6, were for the specialists and consisted of parallel sessions devoted to pion and nucleon physics, strange particle physics, cosmic-ray and high-energy physics, and the theory of elementary particles Following the week-end, which was free of scheduled lectures, there were three days of plenary sessions at which the results of the previous sessions were intended to be summarized and put into perspective for the conference as a whole by 'rapporteurs', one for each subject division Naturally, with so much information reported and discussed, the 'rapporteurs' had no easy task and their lectures to the plenary sessions as given in the *Proceedings* show that many quite openly admitted their inability to summarize or survey the work presented at the conference They dealt generally with one or other aspects of the particular topic assigned to them Nevertheless, with the whole of the *Proceedings* available to the reader there should be no difficulty in finding out the progress reported in any special field

Prof V F Weisskopf, director-general of CERN, gave the concluding address and in his brief remarks surveyed in a masterly and clear fashion the progress achieved both experimentally and theoretically in high-energy physics during the years between 1960 and 1962 Many new facts had emerged Results obtained from scattering experiments of nucleons by nucleons or pions by nucleons show that the nucleon at very high energies gets more diffuse and larger so far as scattering with strongly interacting particles is concerned It implies the absence of a core The various groups of isobars, in particular the baryons and their excited states now seem to fit in well with the simple quantum numbers, but it is still unknown what this means There are indications, too, that the list of the excited states is limited, unlike the excited states of the hydrogen atom The discovery of the existence of two neutrinos has opened up a new field of research, neutrino physics, and a special session of the conference was devoted to the neutrino experiment, which was described by M Schwartz Members of Columbia University, New York, and of the Brookhaven National Laboratory, conducted the experiment in which it demonstrated that the neutrons emitted in π–μ decay differs from that emitted in nuclear β decay The increasing amount of evidence that the muon is equal to the electron in all its properties except that of mass, and other details about weak interactions, such as whether the $\Delta Q = \Delta S$ rule holds, or whether the isotopic spin changes by more than $\frac{1}{2}$, leave, however, weak interaction theory still much where it was in 1960, in spite of more than 300 papers on the subject during the two years between the conferences This is the conclusion arrived at by L B Okun of the Institute of Theoretical and Experimental Physics, Moscow, who acted as 'rapporteur' for the sessions on weak interactions (theoretical) His report is followed by a bibliography for the period January 1961–May 1962 in which are listed some 320 papers.

Prof Weisskopf concludes with the remark that we do not understand the meaning of what we observe "We are trying, not without success, to introduce analogies and ways of speaking It could be that all we have found follows from field theory The theoretical situation is problematical but full of interesting ideas The experimental situation is very much better than anyone would have guessed two years ago The world within the nucleon is much richer and much more interesting than we ever expected "

The *Proceedings* lists 357 scientists in addition to those from CERN as having attended the conference and altogether some 760 people participated in the conference either as authors of papers or in the discussions At the first conference in 1951 there were only about 50 participants It is difficult to forecast what will be the number at the next conference in 1964 at the Joint Institute for Nuclear Research, in Dubno, and whether the progress to be reported will be significant and worthy of the very large effort now devoted to high-energy physics. The next *Proceedings* will doubtless have to be published in two volumes S WEINTROUB

TRANSISTOR COMPENDIUM

Der Transistor

Physikalische und technische Grundlagen Von Dr H Salow, Prof Dr H Beneking, Dr H Kromer und Dr W v Munch (Technische Physik in Einzeldarstellungen, Band 15) Pp viii+426 (Berlin, Gottingen, Heidelberg Springer-Verlag, Munchen J F Bergmann, 1963) Dm 82

THIS book is in effect a collection of four monographs, each of which was written by one of the authors, as follows (1) "Physical Background of Transistors" (Kromer, pp. 73); (2) "Technological Background of Transistors" (Salow, pp 137), (3) "General Circuit Theory of Transistors" (Beneking, pp 139); (4) "Physical and Technical Properties of Transistors" (von Munch, pp 64)

Part 1 starts immediately with the electron energy band model, then passes rapidly through carrier statistics and current transport phenomena to the theory of the plane *p-n* junction diode and *p-n-p* transistor In both cases, as is to be expected, the author deals with both the 'diffusion' and 'drift' type of device, although the treatment is necessarily condensed Finally, some of the ways in which the behaviour of practical transistors depart from the simple low-injection-level, one-dimensional theory are discussed

In the second part, there is a relatively detailed account of the methods of growing cystals of germanium and silicon and of the various etchants which are used for surface treatment there are some beautiful photographs of etch pits This is followed by an account of the various processes by which transistors of different geometrical construction and impurity profile are made, the reasons for the different geometries being given It is arguable, however, whether or not too much emphasis has been given to this part Although a considerable amount of detail has been presented, it is obviously not enough to enable an uninitiated reader either to grow a crystal or to make a device, it would therefore seem better to err on the side of giving too little rather than too much In Part 3 the author deals with the usual topics of bias stabilization, small-signal parameters, and equivalent circuits (with a bias to the hybrid-π) and then proceeds to examine amplifiers, with particular reference to stability, and oscillators Finally, switching properties are considered

The last part is of limited scope, dealing in the main with circuits for the measurement of the h-parameters in the low-frequency and high-frequency bands, and the effect of temperature on static characteristics There is a brief reference to the measurement of noise at low frequencies The section is concluded, out of character, with a series of short descriptions of 'other junction devices'

In general it can be said that each author has contributed something useful to the whole, but that the work lacks cohesion and the emphasis is not evenly distributed One would like to have read more of avalanche breakdown and noise, which are very cursorily dealt with, and less of crystal growing Part 1 could have been expanded considerably with advantage None the less, the book is not without value as it stands Although it cannot be regarded as a useful introductory book to the serious student of transistors, it will no doubt be a very useful adjunct to such a book—for readers of German F J HYDE

TELEMETRY

Telemetry

By R E Young (Temple Press Monographs on Rockets and Missiles) Pp vii+78 (London Temple Press Books, Ltd, 1963) 17s 6d

THE cover note claims that this book sets out to give a comprehensive treatment of the subject of telemetering in missiles which will be suitable both for students and those engaged in the testing and manufacture of missiles I am afraid that both groups will be disappointed

In particular, I think that the student would, for his own good, be well advised not to read this book because of the vague and often incorrect statements it contains It consists of five chapters which deal with a variety of subjects, including some very elementary standard proofs concerning transmission lines, aerials and receivers

Unfortunately this elementary mathematics has suffered in some instances from printer's errors or incorrect extracting from the original reference Mistakes like this can only confuse the student so that when the author adds in parenthesis "see any standard text-book on transmission lines" this is undoubtedly a sound piece of advice

Modulation methods, a most important subject in radio telemetering, are dismissed in very general terms in only three pages, no mention being made of wideband improvement and the significance of modulation index in frequency modulation systems The emphasis on high-speed oscillography and the treatment of data handling in general are not in line with modern practice nor are the arguments the author uses in discussing digital telemetry particularly valid

Many of the facts and figures quoted as typical of present practice are wrong For example, when describing the use of a piezo-electric material in vibration transducers the author states that barium titanate is suitable in temperature environments up to 250° C without any deterioration of its properties This temperature is, of course, above the Curie point of the materials

It is impossible to detail in a short review many of the inaccuracies regarding limiters, discriminators, commutation and the generation of telemetering waveforms Perhaps the greatest single criticism is the fact that after a number of vague references throughout the book the reader is left with no clear and concise picture of typical British telemetering systems Since this is probably the first book to be published in Britain on this subject it would have been a good opportunity to record the contributions made to the art by scientists and engineers in the United Kingdom and Commonwealth

Regrettably it pales to insignificance when compared with American publications on a similar subject

M A PERRY

CARCINOMA OF THE UTERINE CERVIX

Het Experimentele Carcinoma Colli Uteri

(English Summary—Résumé Français) Door Dr Michel Thiery Pp 542 (Brussels Arscia Uitgaven N V, Presses Académiques Européennes S C, 1963) n p

IN this research monograph, the experimental induction of carcinoma of the uterine cervix is described in considerable detail The anatomical and methodological information will be very valuable to experimentalists in the field, and some of the observations on the progression of cellular atypia and carcinoma *in situ* to frank invasive carcinoma will provide ammunition for those who now press for mass screening of the human female population by cervical smears or other methods

The first three chapters are devoted to descriptions of the experimental methods used and of the anatomy of the test animals The favoured technique involved the repeated painting of the uterine portio with a suspension of 3,4-benzpyrene in acetone under direct vision Mice of several different strains and hamsters proved more or less responsive to this method of tumour induction, rats and guinea pigs were resistant Mice were used in most of the investigations

Chapters 4 and 5 are concerned with the histopathological features of the lesions observed in treated animals hyperkeratosis, epithelial dysplasia, carcinoma *in situ*, and squamous cell carcinoma The close parallelism between these induced lesions and 'spontaneous' lesions of the human cervix is stressed Particular attention is directed to the histopathological diagnosis of early stromal invasion, the features of the subepithelial connective tissue layer which takes the place of the basement membrane in the mouse, and to the squamo-columnar junction Cyclical variations in the vaginal epithelium continued during treatment though their timing was frequently disturbed The majority of tumours were squamous cell carcinomas, but one-fifth of them were mucoepidermoid in nature Finally, modes of local spread and metastasis are considered and the occurrence of associated pathological conditions reported

Chapter 6 is perhaps the most interesting and valuable of the whole book it is concerned with the histochemical characteristics of normal and pathological cervicovaginal epithelium Both glycogen content and the presence of periodic acid–Schiff-positive mucus showed cyclical variations The former does not aid in distinguishing different grades of preneoplasia or neoplasia, it only provides evidence of the degree of cellular differentiation of the lesion Differences in the histochemical patterns of –SH– and –SS– group reactivity were observed between normal and pathological epithelium, but differences between different lesions were not sufficiently marked or constant to be of value in differential diagnosis

The DNA content of the basal nuclei of squamous epithelium was found normally to reach a maximum during œstrus, keratinization was associated with a decrease in DNA content In the abnormal hyperkeratotic epithelium of treated animals, however, the DNA-level was as high as for œstrus epithelium, even in sprayed animals In general, there seemed to be a positive correlation between the DNA value and the position of the lesion on the progressive path between pre-neoplasia and neoplasia, and the author concluded that Feulgen-histophotometry might be a valuable diagnostic tool From a study of the levels of sixteen different enzymes, the author inferred that enzyme histochemical procedures can be successfully applied to the identification of specific cell-types and to the differentiation of various pathological lesions In particular, he was impressed by the fact that squamous cell carcinomas showed a very high 5-nucleotidase activity which made their detection in lesions at the stage of early stromal invasion a relatively simple matter

In the penultimate chapter the evidence for the precancerous nature of various lesions is reviewed, and the *tempo* of their progression to neoplasia discussed Finally, a comparison is made between the experimental tumours and those arising in the human cervix Despite anatomical and genetic differences, the author concludes that "on the whole the parallelism is truly striking For this reason the experimental tumour might eventually offer new opportunities for the study of certain aspects of cervical carcinoma in man"

The book is well written, well illustrated, well documented and well produced, its greatest limitation for most workers is that it is written in the Dutch language

CHANGES OF CLIMATE

Changes of Climate

Proceedings of the Rome Symposium organized by Unesco and the World Meteorological Organization (Arid Zone Research—XX) Pp xii+488 (Paris Unesco, London H M Stationery Office, 1963) 28 francs, 40*s* , 8 dollars

THE study of climatic change is an attempt to reduce into some semblance of order changes in the Earth's climate on diverse scales in both space and time It must consider the operation and effect of a large number of geophysical mechanisms, and involves the collation of results from many different scientific disciplines It is an open secret that, perhaps because the subject is so complex, specious arguments have tended to go unchallenged and occasional dubious conclusions have found their way into text-books of climatology A forum was obviously needed where ideas could be presented and criticized the October 1961 symposium in Rome provided this The volume under review contains the text of forty-five papers presented at the symposium together with a brief summary of the ensuing discussions.

Throughout the volume a laudable concern is shown for the physical significance of results, particularly those inferred from analyses of time series There is a distinct tendency to adopt a more precise approach to the subject than hitherto Also it should be noted that the problem considered was to assess whether any significant changes in climate can be resolved from available data and to understand the mechanisms involved, it was not to attempt any prediction of future trends The papers are divided into four main sections

The first section deals with changes during the period of meteorological records Most of these papers try to show the way in which the evidence falls into a pattern in which the physical significance depends on the combined results of several different variables However, even when distinct trends can be firmly established there was difficulty in interpreting these in terms of what had happened to the atmospheric circulation Section 2 is devoted to changes during late geological and early historical records The net result here is to show how various disciplines can combine to pose questions which meteorologists, without a quantitative theory of global climate, find great difficulty in answering Occasionally in the first two sections there is a tendency to consider mean atmospheric and mean oceanic circulations as though they are complete physical entities in themselves rather than part of a statistical description of highly fluctuating flow-patterns This is particularly noticeable when cause and effect are discussed the importance of deviations from the average flow (eddies) were sometimes forgotten There are obviously many interrelated mechanisms going on that are extremely difficult to assess adequately in a qualitative way, and one is left with the feeling that a more precise treatment along the lines indicated by the papers in the next section is urgently required

Theories of changes of climate are the subjects of Section 3 Here there is a call for an attempt to produce a rough model which can represent realistic seasonal variations, later the model might be used to discriminate between likely and unlikely hypotheses A pointer to the probable line of future attack is given by two papers using a quantitative approach and extremely simple models to describe the effect of a hypothetical increase in solar constant, and to test the validity of possible mechanisms of climatic change Simple numerical techniques might well be profitably applied to some of the other theories advanced Section 4 concerns the significance of changes of climate —on vegetable cover, patterns of land use, geomorphological features, etc The importance of *variability* of rainfall to agriculture in semi-arid regions is emphasized, and the final paper stresses the practical implications of statistically insignificant changes in climate when a threshold, peculiar to the area and the crop, is crossed

The whole publication is excellently produced in a paper-covered volume, but a summary of each paper in English as well as in French (vice versa for some papers) would have improved the presentation For nearly 500 pages of valuable material the price is extremely low

RUSSIAN APPROACH TO FISH ECOLOGY

The Ecology of Fishes

By G V Nikolsky Translated from the Russian by L Birkett Pp xv+352 (London Academic Press, Inc (London), Ltd , New York Academic Press, Inc , 1963) 75*s*

THIS most stimulating book is especially welcome for three reasons First, no other book covers the same ground, and it should be a very useful reference work for both academic biologists and those concerned with fishery problems Secondly, this book and English translation make the great contribution of Soviet ichthyologists and ecologists available to the many who cannot read Russian Thirdly, and in the long run perhaps most important, this book is to be welcomed for its refreshingly unifying approach to biology

Throughout the book one is aware of Prof Nikolsky's appreciation of the unity of the organism and environment, and that it is the adaptive interactions to particular elements in the environment which ensure the development and existence both of the organism and of the species It is made quite clear that ecological studies must be based on knowledge of the structure and functions of the organs, and that such studies, at all stages of the life-cycle, make the only basis for rational fishery development

The book is divided into three parts In the first, Nikolsky considers "Interrelationships between Fishes and their Abiotic and Biotic Environment" It is here that the reader is most conscious of Nikolsky's continual awareness of the interchange between the organism and all the many facets of the environment proceeding simultaneously some factors having greater effect at one stage of the life-cycle and others at another, some having greater significance at one stage of the evolution of the species and others at another, a continual flux and web, with continual interaction of the different factors This interaction so often appears to be forgotten by those designing ecological experiments

The abiotic relationships considered are the density and pressure of water and adaptive changes of the swim bladders of different fish groups, water salinity and osmoregulatory mechanisms, gases in solution and adaptations for aerial respiration, the effects of temperature, light, sound, electrical and electromagnetic forces, and the fishes' reactions to bottom deposits and water movements There is also mention of work on X-rays and radioactivity on fish, very relevant to the modern problem of dumping atomic waste From experience in high latitudes, attention is directed to the many ways in which ice affects fish

The discussion on biotic relationships begins with those which are intraspecific This includes a useful summary of work on shoaling in fishes, of great importance for the design of fishing gear When discussing interspecific relationships, Nikolsky comments on the differences in faunistic complexes at different latitudes, the more intensive predator–prey relationships in lower latitudes with corresponding increase in the development of protective adaptations (such as great fecundity, care of young, armour), and that lower-latitude fish tend to be more stenophagic The interrelationships of fishes and other organisms are then treated group by group, from bacteria, viruses and plants, and from Protozoa to Mammalia, whether these other organisms be food or enemies of the fishes.

The second part of the book, entitled "Fundamental Links in the Life Cycles of Fishes", is a series of discussions on reproduction and development, size, growth and age of fishes and ways of estimating these, population dynamics, migrations, overwintering and hibernation behaviour, and feeding relationships There is inevitably some repetition of Part 1

Part 3 is much shorter, and a discussion on the significance of fishes in the life of mankind and the biological basis of a rational fishery Here it is emphasized that fundamental knowledge of the ecology and behaviour of the fish, at all stages of the life-cycle, is the only rational basis for fishery development One point raised is that whereas in temperate waters much can be done to manipulate age classes of fish to give highest sustained yields, in tropical waters production is unlikely to be increased by this method, as the life-cycles of the fishes are so much shorter and age groups represented in the catchable population fewer

To compress the whole 'ecology of fishes' into some 300 pages is bound to lead to generalizations which are rather sweeping and thereby lose in accuracy, and some of the parts concerning fishes outside the U S S R have to be read with discretion A rather surprising omission when discussing the role of cœlenterates in the lives of fishes is that there is no mention of corals, and the whole groups of fishes which gain food and shelter from them References to work in the tropics, for example, are rather out of date One particularly puzzling point, to which no reference is given, is the "intestinal incubation of eggs in *Tachysurus barbus*" figured Could these possibly have swallowed their eggs when disturbed, as fishes practising oral incubation so often do ?

One is very grateful to the translator for making this book available in English, but the impression is given that he is not a zoologist The choice of "abiotic" for 'physicochemical factors' becomes misleading in some contexts, and "upstream" is used when 'higher up in the water' is probably meant Curious punctuation occasionally gives misleading ideas, and one could wish that the English names used for the fish were the common ones, as the names used are sometimes confusing (The translation of Nikolsky's *Special Ichthyology* seems more successful in this respect)

The 140 figures illustrating the text are helpful, though a few graphs lack information concerning the units used, or which curve is which Three figures present a visual summary of the biotic links in the sea and fresh water and "the proper and improper conduct of a fishing industry"

Despite minor drawbacks, this is a splendidly stimulating and thoughtful book, which should have a profound effect on the approach to fish ecology It is a book which should be in the possession of every ecologist interested in fish, and of all those concerned with the management of fisheries, though the price is unfortunately high

R H McConnell

DEVELOPMENTS IN PARASITOLOGY

Advances in Parasitology

Vol 1 Edited by Dr Ben Dawes Pp xvi + 347 (London Academic Press, Inc (London), Ltd , New York Academic Press, Inc , 1963) 70*s*

It is not possible, in a relatively short review, to tell prospective readers of the wealth and detail of the information contained in this well-written and well-produced book

Introduced by a short preface by its editor, Prof. B Dawes, the book begins with two chapters devoted to the parasitic Protozoa In the first of these, Clay G Huff sums up recent researches done on the species of *Plasmodium*, *Haemoproteus* and *Leucocytozoon* parasitic in birds. This valuable article contains a detailed section on the avian species of *Plasmodium* which discusses the natural immunity and susceptibility of the avian and mosquito hosts, the effects of X-irradiation on the development of these Protozoa in their mosquito hosts, the cytology and genetics of the species discussed, the growth of their sexual phases *in vitro* and *in vivo*, the development of the gametocytes and their infectivity, the periodicity of the asexual multiplication, the effects of viruses, bacteria and yeasts and coccidia on the parasites, their cytochemistry, fine structure, immunology and pathology and their exoerythrocytic phases Shorter, but no less interesting, sections follow on recent work on *Haemoproteus* and *Leucocytozoon*

In the second essay on Protozoa, C. Horton-Smith and P Long discuss the pathology and life-cycles of the species of *Eimeria* which cause coccidiosis of the domestic fowl and the turkey, the oocyst production of these species, the DNA, RNA and other chemical substances encountered in the coccidian life-cycle and modern knowledge of the immunology of this economically important disease

The rest of the volume is devoted to parasitic nematodes and to the larval phases of monogenean trematodes. A valuable essay by W P Rogers and R I Sommerville describes in detail the significant and promising work that has been recently done on the infective stages of parasitic nematodes and their significance in parasitism In a short review it is impossible to indicate the importance of the investigations here described They include studies of the nematode life-cycle as a whole, the physiology, behaviour and survival of the all-important infective stages, the process of infection of the host by these stages through the gastro-intestinal tract or through the skin and the problems faced by the nematode when it has to pass from the world outside the host to the environment it encounters inside the host's body The mechanisms of the vital ecdyses are here involved, and the authors discuss the problems of infectiousness and their hypothesis of infectiousness considered as an adaptation to parasitism

In the next article, D Poynter discusses the lungworm of cattle, *Dictyocaulus viviparus*, which causes parasitic bronchitis, or husk, in cattle, the pathology of this economically important disease, the biology of the infective stages on the pastures from which the cattle pick them up and the remarkable recent use of X-irradiated larvæ of the parasite, to make the vaccine developed by workers at the Glasgow School of Veterinary Medicine, which is proving an effective means of protecting cattle from the disease. This vaccine marks a 'break-through' in the field of the immunology of parasitic infections the importance of which can scarcely be overestimated

There follows a useful article by John E Larsh, jun , on recent work on experimental trichinasis in hamsters, rats and mice, and the volume concludes with an article by J Llewellyn on the morphology of the larvæ of monogenean trematodes and their post-miracidial development

So rapid have been the advances in our understanding of the parasite as an organism living, like other creatures, in conflict with the risks of its mode of life and with the challenge of its environment, that everyone who has to deal with parasitic life can scarcely afford not to read this book and to learn how the application of the methods of biochemistry, biophysics and experimental biology in general have altered, in a few productive years, the whole structure of this branch of biology The promise of this kind of work is incalculable Not only the biologist but also the medical man and the veterinarian and everyone else who is concerned with the mitigation of the suffering and loss of life inflicted by the parasite will welcome this volume and will hope for successors to it which will deal with the fields of work not covered in these pages

G. Lapage

Photo-Electronic Image Devices

Proceedings of the Second Symposium held at Imperial College, London, September 5–8, 1961 Edited by J D McGee, W L Wilcock and L Mandel (Advances in Electronics and Electron Physics, Vol 16) Pp xv+654 (New York and London Academic Press, 1962) 130*s*

ADVANCES in photo-electronics have largely centred around image devices, photomultipliers and other components for converting radiation into electronic signals The spur to increase sensitivity, signal/noise ratio and spatial resolution and to improve reproducibility has kept technologists busy and has led to excursions into allied branches of applied physics, particularly electron optics and vacuum technology The discovery of new physical effects likely to have far-reaching influence is not at present a primary aim of the subject, which, however, does not lack effects requiring clarification and justification on fundamental grounds If the subject is compact, that is more than can be said of the workers in it, many of whom owe their first allegiance to particular fields of application Prof McGee, in organizing two symposia on the key-image devices, has thereby brought together scientists who might otherwise never have met

The report on the second symposium on "Photo-Electronic Image Devices", held at the Imperial College of Science and Technology during September 5–8, 1961, is very factual, it shows no diminution of activity since the 1958 symposium, stresses the attention being directed to details to improve performance and leaves no doubt as to the contributions being made by users (compare the transistor, for which no user has also been a designer or technologist) Several astronomers are now using electronic cameras following pioneering work by Lallemand, Duchesne and a few others The precautions needed to prevent the photographic plate spoiling the vacuum and hence the photocathode are central themes of two papers, a bakeable electronographic plate may still be required, however, despite its inability to match the large gain conferred by the conventional developing of a photographic plate Image intensification is a fruitful subject at the moment and has received much attention, the television camera tube, on which so much effort has already been expended, did not figure so prominently, but infra-red and ultra-violet versions were described Nuclear physicists are extending the versatility of scintillation counters, as several papers show, and further progress can be expected, based on applying techniques developed for other devices

One or two laboratories surveyed their own work over the past few years, but review papers were otherwise absent, their inclusion in any symposium is a gamble for they may turn out to be mere catalogues or to be insufficiently critical But two or three good reviews here would have improved an already impressive and readable report

J R TILLMAN

Diseases of Turfgrasses

By Prof Houston B Couch (Reinhold Books in Agricultural Sciences) Pp xiii+289 (New York Reinhold Publishing Corporation, London Chapman and Hall, Ltd, 1962) 80*s* net

THE production and maintenance of high-quality grass turf, whether for ornament or recreation, requires skilled management which involves effective control of diseases affecting turf grasses A comprehensive treatment of this specialized topic would certainly be welcomed by turf specialists and plant pathologists, it is disappointing, therefore, to find that Prof Couch's book does not fulfil the promise of its title

The main text of the book occupies 180 pages and is divided into four chapters, the first of which deals briefly and in very general terms with the nature and causes of disease in plants Chapter 2 (124 pp) is concerned with fungal diseases These are well described and the control practices (where any are available) are clearly explained The coverage on fungal diseases is certainly comprehensive and includes many diseases (for example, those affecting inflorescences, such as smuts and ergot) which might well have been omitted Indeed, their inclusion only serves to exaggerate the omissions referred to below The third chapter deals concisely with nematodes, and the main text concludes with a short chapter on the fundamentals of disease control

Two notable omissions from this book are physiological and virus diseases Their exclusion can scarcely be justified in a work which claims to be comprehensive To be told (p 5) that physiological diseases are already well covered in standard works on turf-grass management will scarcely satisfy the plant pathologist, particularly when no specific references to sources of information are given Equally the omission of virus diseases, apparently on the grounds that "information concerning them is not yet sufficient to evaluate properly their importance", is scarcely acceptable The same might be said of a great many of the fungal diseases described The omission of virus diseases is all the more serious because recent work is showing that they may, in fact, be seriously damaging in agricultural swards, presumably they may be equally important in sports turf and lawns The inclusion in this book of the symptoms, host-ranges and mode of transmission of the many grass viruses now known would have been most valuable if only in directing the attention of turf specialists to this group of diseases

More than a third of the book is devoted to five appendix tables Apart from the first (which is a short list of fungicides and nematocides), these constitute a particularly clear index of diseases and host species cross-referenced under their common and technical names Certainly in this 100-page appendix the reader will have no difficulty in locating the items of information contained in the other 180 pages

ELLIS GRIFFITHS

The Morphology of Pteridophytes

The Structure of Ferns and Allied Plants By Dr K R Sporne Pp 192 (London Hutchinson University Library, 1962) 12*s* 6*d* net

THIS condensed but clear account of the morphology of the pteridophytes is evidently aimed primarily at an undergraduate public Available at a most reasonable cost, it will surely be deservedly popular as a student text An excellent feature of this book is the attention directed to the integration of the results of modern research with classical morphology Not only are more obvious discoveries like *Stylites* described, but also recent developments in all aspects of the subject are included Rather more than half the ninety items included in the bibliography were first published since 1945

Great pains have evidently been taken over the production of the beautifully drawn figures, which are a joy to study Nevertheless, one must regret that it has been found necessary to overcrowd the illustrations on certain of the figures (for example, Figs 14–17), so as to confuse the eye, and to over-reduce certain of the illustrations (for example, Figs 12*A*, 16*E*, and 17*A*) to such a degree that their evident quality is obscured One appreciates with approval the intention to keep the price of this book as low as possible, but it is a pity that a larger page-size could not have been used

Errors appear to be commendably few There is an unfortunate misprint on the fourth line of p 166, where *Phyllitis* is intended but *Athyrium* is printed, which may seriously mislead the unwary It is not true that there are eleven species of *Equisetum* in the British flora, and *Phylloglossum drummondii* occurs also in south-western Australia, but these are small blemishes in an admirable text This book is a valuable addition to the botanical literature, and is most warmly recommended

J D LOVIS

LYON PLAYFAIR, 1818–98*

By PROF R. V. JONES, C.B, C B E

Department of Natural Philosophy, University of Aberdeen

THE Scottish family of Playfair has an extraordinary record of distinction in public service There have been Playfairs in high positions in medicine, the law, the armed Services and the Civil Service Playfair of the axiom was both an eminent mathematician and a geologist Another member of the family was Principal Playfair of St Andrews, who was in office from 1800 until 1819 He married a Miss Lyon, a relative of the Lyons of Glamis, and they had four sons The eldest of these, George, went into medicine and served, as so many of the family had done, in India, he became chief inspector-general of hospitals in Bengal He married a Miss Ross of Edinburgh and, of their four sons and three daughters, it is their second son, Lyon, born at Meerut on May 21, 1818, who is of especial interest now

The boy returned to Scotland in 1820, and in due course went to the parish school This he said was excellent Of his later education at a grammar school he was not nearly so complimentary In his autobiography he says "To my mother and her surroundings I owe all my early knowledge, precious little of which I derived from the Grammar or Classical School to which I was sent at a later period" He retained, as will be seen, this critical attitude to the then current form of education throughout his life His best holidays, he says, were spent with his grand-uncle, a minister, in the manse at the gate of Glamis Castle

At the age of fourteen he was enrolled as a bejant in the University of St Andrews, and attended the ordinary courses for the M A degree Of the subjects in the course, mathematics pleased him most, but he broke away from his curriculum whenever possible to slip into the lectures in chemistry and natural philosophy After this, he was sent to work as a clerk in the office of his Uncle James, a merchant in Glasgow His fellow clerk was named Ramsay, and when, after a short experience of mercantile life, he obtained his uncle's permission to study for medicine, he went to board at the house of Ramsay's mother The Ramsay family is worthy of mention, since one of Mrs Ramsay's grandsons was the famous chemist of University College, the discoverer of helium on the Earth (in 1894)

Instead of going straight into medicine, Playfair decided to study chemistry seriously, since it was his favourite subject, he therefore chose to go to the Andersonian College (now the Royal College of Science and Technology in Glasgow) rather than to the University itself, because this would give him an opportunity to study with Graham, who was professor at the College, and one of the most distinguished chemists of his time In Graham's classes there were two students of a similar age to Playfair with whom he formed friendships The first of these was David Livingstone The second student was James Young, who, as James Watt had been before him, was employed to repair laboratory instruments He had been engaged by Graham as an assistant, and was later to participate with Playfair in the foundation of the shale oil industry

After Playfair had been with him for two years, Graham was called to University College, London Glasgow thereby lost its attraction for Playfair, who moved over to Edinburgh to carry on with his medical studies He obviously enjoyed the social life of the University, and helped to form a dining club which developed into 'The Red Lions', a famous social function of the British Association Playfair had to stop his medical studies, since he contracted eczema, and he left for India on his father's advice Again he started in a mercantile career, this time in Calcutta, but once again his interest strayed back to chemistry, and he gained the acquaintance of the professor of chemistry in the local college The professors there advised his father to send Playfair back to England, and he therefore returned in 1838 to join Graham at University College In 1839 Graham advised him to go to study under Liebig at Giessen

Liebig at this time was writing his great book on agricultural chemistry, and he invited Playfair to undertake the English translation Liebig's views were to be announced in a general way at the 1840 meeting of the British Association in Glasgow, and since Liebig himself was unable to go, Playfair went to represent him and was promptly appointed secretary of the Chemistry Section

Industrial Chemistry

Playfair returned to Giessen and graduated as a doctor of philosophy, but the Glasgow meeting had given him the opportunity of meeting various chemical manufacturers, and in the spring of 1841 he accepted an offer from a Mr Thomson of Clitheroe to become chemical manager of his print works

Playfair knew nothing of the process of calico printing, but he quickly saw that Mr Thomson's works were likely to fail sooner or later, since Thomson insisted on expensive hand productions, which were unlikely to survive in the competition with mechanical reproduction processes. Playfair therefore thought of moving, but before he left Clitheroe, he encountered the great labour riots of 1842 in Lancashire The rioters were out to smash the machines, and Playfair went to the rescue of a neighbouring mill He met the advancing rioters, and told them that he was perfectly well aware that their force was irresistible, and that they could stop the works He suggested to them that instead of doing widespread damage, they could secure their object of stopping the works by removing the plugs from the boilers They accepted his offer of acting as a hostage, while they removed the plugs Characteristically, he afterwards recorded that from the conversations that he had with them during his detention, many of their demands were reasonable

While at Clitheroe, he gave several lectures in Manchester, and accepted the office of honorary professor of chemistry in the Royal Institution in Manchester This brought him into contact with several men of distinction who were at that time in Manchester, most notably Dalton and Joule Dalton was president of the Manchester Literary and Philosophical Society, and was re-elected annually There was always one dissentient vote in the ballot, Playfair says, this was that of Dalton himself, who used to vote for one of his friends On the last vote before Dalton's death, there was the one dissentient vote as usual—but this time Dalton had voted for the door-keeper

In October 1842 Playfair was surprised to receive a letter from Faraday, offering him the professorship of chemistry in King's University, Toronto Playfair thereupon visited Faraday in London, and indicated that he would like to accept the proposal This intention was not, however, favourably regarded by various of Playfair's friends in London, who thought that his loss would be too serious A few days later, to his great surprise, Playfair received an invitation from Sir Robert Peel, who was then Prime Minister, to visit him at Drayton Manor, his home near Tamworth Playfair thought that this letter might well be a practical joke, and spent a day or two checking its authenticity He then went to stay with Peel for a few days, and Peel explained to him that several men of science had asked him to persuade Playfair to stay in Britain He even offered Playfair a written promise that he would make it his duty to obtain suitable employment for Playfair in Britain, but the latter would not accept the document, saying that the Prime Minister's appreciation was all that he could have wished

---

* Substance of a lecture given on September 3 before Section X (General) of the British Association for the Advancement of Science meeting in Aberdeen

For a time, Playfair returned to Manchester, but he was quickly drawn into an investigation on behalf of the British Association for the Advancement of Science with Bunsen, who came across from Heidelberg, into the economy of blast furnaces This investigation, which showed that with the existing design of furnaces more than 80 per cent of the fuel escaped from the furnace in the form of gases, resulted in a great improvement in efficiency The report was published in the annual volume of the British Association for 1845 In the meantime, in 1843, Peel had asked Playfair to sit on a Royal Commission into the state of large towns This was the first of the many public committees on which Playfair was to serve, he took a special interest in the large towns in Lancashire, since he was well placed to study them The findings were terrifying Owing to the effect of such features as bad sewerage and overcrowded tenements (one-seventh of the population of Liverpool lived in cellars) the expectancy of life was very short, in Manchester it was twenty-two years, in Liverpool twenty, in Ashton sixteen As a result of the findings of the Royal Commission, on which Edwin Chadwick, the veteran sanitary reformer, was prominent, the conditions in the towns were much improved

Just as this inquiry was drawing to a close in 1845, Peel offered Playfair the appointment of chemist to the Geological Survey, and Playfair became a regular guest at Peel's home, along with such men as Wheatstone and George Stephenson Playfair records how after dinner on one of these parties, George Stephenson put forward the theory that his locomotives derived their original power from the Sun through the plants that were fossilized into coal, the geologists present laughed, and Stephenson gave up the argument Peel afterwards asked Playfair what he thought of Stephenson's view, and the latter told him that it could be supported Peel told Playfair to explain the arguments to Follett, a lawyer, who was also a guest Next evening, the conversation was duly steered in the same direction again, to give Follett a chance to intervene, briefed by Playfair, he completely routed the geologists Stephenson, listening in amazement, exclaimed "Of all the powers in Nature, the greatest is the gift of the gab"

While Playfair was still in Manchester he formed a close friendship with Joule, who was then engaged on his experiments on the conservation of energy Joule and Playfair undertook several investigations together into atomic volume and specific gravity, and published several joint papers in the *Journal of the Chemical Society*, the most important result was the discovery that the increase in the volume during the process of solution of a hydrated salt was due to the water released from the salt itself Playfair persuaded Joule to become a candidate for the chair of natural philosophy of St Andrews, one of the electors, however, objected to a slight physical deformity that Joule had, and so created another instance of a university losing a great opportunity

It is one of the regrettable facts in the history of scientific publication that the Royal Society rejected Joule's first account of his conservation experiments Playfair tells how this was due, among others, to Wheatstone, who was his close personal friend Playfair and Wheatstone spent a whole Sunday afternoon walking on Barnes Common discussing Joule's experiments and their consequences, if true, to science Playfair failed, unfortunately, to convince Wheatstone, and so the Royal Society rejected the paper Playfair continued his work with Joule, after he transferred to the Geological Survey, the main premises of which were in Jermyn Street, London He himself had a temporary laboratory in Duke Street, here he discovered the nitroprussides Among his assistants were Edward Frankland and James Dewar. The Geological Survey ran the Geological Museum which developed, under the directorship of Henry de la Beche, into the School of Mines

Playfair's attempts to pursue his researches became increasingly interrupted by Government demands on his services The first of these was to report on the state of Buckingham Palace Playfair found, after some drastic experiments involving the explosion of gunpowder with some olfactory mixture in the Palace kitchen, that the carbon monoxide fumes from the charcoal fires were ascending into the royal nurseries The sewerage system was also rudimentary. Playfair's report was so frank and brutal that the Government did not dare to publish it He had also to look into the state of Eton College, and the Board of Health asked him to report on graveyards, from which experience he became an advocate of cremation, and to analyse all the water proposed for the supply of towns The Admiralty asked him to determine the best coals for steam navigation, Playfair was connected with this investigation for many years

Another field of activity for Playfair about this time was that of safety in mines Lyell and Faraday were Government commissioners, and had reported on the dangers of fire-damp This was, of course, a considerable time after the invention of the safety lamp, but there was still much carelessness in the mines, and explosions were repeatedly occurring Playfair was asked to investigate a particularly bad explosion at Jarrow, apart from investigating the explosion itself, Playfair conducted a programme of analysis of fire damp from many mines His direct connexion with safety in mines did not last very long; but years afterwards it turned out to be valuable A serious strike of miners was imminent in the Newcastle district, and, although he was in Brittany at the time, both the owners and the men decided to send for Playfair to arbitrate between them The strike was averted

The Corn Laws

The investigations that Playfair was called on to undertake took him farther and farther away from pure science As one of these tasks he was asked to report on the foul state of the Serpentine At this period, by far the most important of the investigations that he was asked to carry out was one in the autumn of 1845, when Peel sent for him and told him how worried he was about the effects of the potato disease in Ireland Peel asked Playfair to nominate two others to act with him on a commission of inquiry, and to report Playfair found that the prospect for Ireland was starvation, and he reported to Peel that this would be so unless the Corn Laws were repealed This obviously placed Peel in a very difficult position, since his own party was responsible for the Laws Peel replied to Playfair "I am indeed sorry that you are compelled to make so unfavourable a report, but the knowledge of the whole truth is one element of security" This readiness of Peel to face unpleasant facts shows why Wellington said of him "Of all the men I ever knew, he had the greatest regard for truth" It is, of course, one of the most celebrated incidents in Britain's history of party government how Peel turned on his own party, and carried the repeal of the Corn Laws, in view of the present interest of the functions of science in Government, it is interesting to realize that Peel had a man of science behind him.

The Great Exhibition of 1851

The culmination of all this public work came in Playfair's appointment to a key position in the planning of the Great Exhibition of 1851. This Exhibition had probably started as a concept of the Prince Consort and Sir Henry Cole. The Society of Arts organized a committee to carry through the arrangements, but the task was really too great. A Royal Commission was therefore formed, containing eminent men of both political parties. The detailed arrangements were in the hands of an executive committee, substantially with the membership of the body previously selected by the Society of Arts. However, the two bodies were in danger of drifting apart, and Peel asked Playfair to be a member of both bodies to ensure that they kept in step. Playfair himself had misgivings about leaving his scientific work, and objections were raised by his fellow professors on the grounds of the upset to their teaching programme. Peel again intervened, this time so strongly that neither Playfair nor his colleagues could refuse.

Playfair at once came into close contact with the Prince Consort, and this rapidly developed into friendship. One of Playfair's many contributions was to organize the classification of the various sections. His system was accepted by all the authorities concerned, including the foreign representatives, with the exception of France, since the French had devised a logical and philosophical classification for themselves. Playfair and the French representative agreed that they should test the rival classifications by seeing how easy it was to classify a simple object on the two systems. The Frenchman suggested that they should try his walking stick. Playfair turned to his class of 'Miscellaneous Objects' and soon found the walking stick under the sub-section 'Objects of Personal Use'. The French Commissioner looked for a long time in vain through his logical classification, but ultimately found it under the heading 'Machines for the Propagation of Direct Motion'. Playfair's system was thereupon adopted.

Much of the success of the Exhibition must have been due to Playfair's wisdom and energy, the Prince Consort was very impressed and offered him the post of Gentleman Usher in his household. In this position, Playfair was very frequently consulted by the Prince on all kinds of matters. The Exhibition building, originally erected in Hyde Park, was taken down and erected again in 1854 at Sydenham as the Crystal Palace. As part of its educational value, it was to be decorated with copies of great statues from all over the world, along with an ethnological collection of effigies of savages. Playfair records that most of the figures were nude, and that just before the opening there was a written representation to the Queen, signed by most of the Bishops, stating that they could not attend the State opening unless all the nudes were properly draped. The Prince Consort called for Playfair's advice, his light-hearted suggestion was that the Prince should ask the Bishops for a loan of their aprons during the ceremony.

In the winter of 1851–52 the Society of Arts organized a series of lectures on the results of the Exhibition, in which the speakers underlined the need for scientific education. In this series Playfair's lecture was outstanding. He held that the Exhibition showed that "wherever a nation used science in its manufactures that nation was in the ascendant", and suggested that "in the establishment of institutions for industrial instruction you, at the same time, create the wanting means for the advancement of science in this country". Playfair also gave two brilliant inaugural lectures at the School of Mines urging the importance of ensuring the developing harmony between the advance of pure science and the progress of industry. The second lecture, which was given in the autumn of 1852, was on "Industrial Instruction on the Continent" and included much information that he had gained earlier in the year when, at the request of the Prince Consort, he had toured the Continent. He pointed to a curious weakness in the national outlook in Britain, which even now has not been fully overcome. "In this country we have eminent 'practical' men, and eminent 'scientific' men but they are not united and generally walk in paths wholly distinct ... from this absence of connexion there is often a want of mutual esteem and a misapprehension of their relative importance to each other". In 1853 he continued this theme in a lecture to the 'People's Club' in Sheffield on "Science in its Relation to Labour".

In August 1851, before the Exhibition had ended, the Prince had roughed out a scheme for using the profits. This involved buying a large area in South Kensington, very near to the site of the Exhibition, and building on it an institution for "the furtherance of the industrial pursuits of all nations". Playfair, with whom the Prince discussed his scheme, favoured a widespread system of centres of technical education throughout the country united with a university of mines and manufactures on the Kensington site. The Prince provided a friendly brake on his enthusiasm by pointing out that Playfair had omitted any reference to religious education in his scheme, and that it might be wrecked by religious opposition on this account. This was not a fanciful objection, for religious bias was formidable: in 1845 Playfair's former master, Liebig, was even disqualified from consideration for the chair of chemistry at King's College, London, because he was a Lutheran and not an Anglican. Following the Prince's wishes, the South Kensington site was in the meantime purchased out of the £186,000 profit of the Exhibition, and, although it took many years, the ultimate formation there of the Royal College of Science is due to the foresight of the Prince, Playfair and their associates.

The Science and Art Department

One step on the way was the formation of the Science and Art Department in 1853, with Playfair at the head of its science side. It was mainly concerned with educational matters, and it founded science schools in various towns. In the course of this work, Playfair paid a visit to Edinburgh, and persuaded the Town Council to provide the land, and the University the original collections, for a museum, he then succeeded in obtaining a parliamentary vote, and thus founded the Scottish National Museum.

The Science and Art Department seems to have had some other functions besides its educational ones, since it was asked in 1852 to design a State funeral carriage to carry the body of the Duke of Wellington. Playfair records that it was made of bronze and was so heavy that it broke a sewer when crossing St James's Park; and this delayed the funeral procession, one of the spectacles of the century, for one to two hours.

At this time Playfair was living in the Putney area, and saw much of Wheatstone, who lived in Hammersmith. They spent many of their Sundays together, amusing themselves by deciphering the cipher advertisements in the personal column of *The Times*. One turned out to be from an Oxford student in a reading party at Perth, who was corresponding with a young lady in London. When he proposed an elopement, Wheatstone and Playfair decided that it was time to step in. They therefore inserted an advertisement in the same cipher reading "Dear Charlie, Write no more. Our cipher is discovered".

About the same time, Playfair frequently saw Babbage, the inventor of the calculating machine, who resented the way that he had been treated by the Government. In the course of trying to improve the public recognition of science, Playfair had suggested to the Prince Consort that it would be a happy gesture to make one or two scientists Privy Councillors, he mentioned Faraday and Babbage as two who were well fitted for this honour The Prince asked him to sound the two men, but while Babbage was delighted with the suggestion, he made it a condition that he alone should be appointed, as reparation for the Government's neglect of his inventions This unfortunate attitude caused the Prince Consort to drop the idea

The prospect of the Crimean War caused Wheatstone and Playfair to submit one of their ciphers to Lord Palmerston, it has since become one of the classical methods of enciphering Playfair produced inventions for incendiary shells and poisonous gas shells, but these were not taken up at the time In 1855 the mastership of the Mint became vacant Playfair would very much liked to have had this appointment, but he found that his late master, Graham, was anxious for it He therefore supported Graham, who was awarded the honour

Chemistry at Edinburgh

In 1858, the chair of chemistry at Edinburgh became vacant Playfair had applied for this post on an earlier occasion, when it was awarded to Gregory On the present occasion, he saw a chance to get back to research, and his attainments and distinctions were such that he would almost certainly get the chair if he applied for it But his friends in Edinburgh insisted that he should have some testimonials One of these he obtained from his pupil, Frankland, now a professor himself His letter to Frankland asks the latter to confirm various of his qualifications, including "that as President of the Chemical Society I have shown that I studied Chemistry"

Playfair had to resign his appointment as Gentleman Usher to the Prince, and he threw his full energies into reorganizing the Chemistry Department He introduced a system of tutorial classes, which rapidly became a feature of other departments throughout Scottish universities He also devised a system of merit certificates, which again extended throughout the Scottish universities He also decided, perhaps from his experience at Court, that graduation ceremonies needed to be revived to produce a feeling of pride among graduates All these reforms are strong features of the Scottish universities to-day

As always, Playfair collected good stories One of his colleagues at this time was James Simpson, who introduced chloroform into surgery Playfair says that in Scotland there used to be an antipathy to objects not mentioned in the Bible, and that on this account, for example, potatoes were only slowly adopted by the Scots This attitude gave Simpson much trouble, since not only was chloroform not mentioned in the Bible, but also it was positively in direct contradiction to the curse on woman that she shall endure sorrow in bringing forth children Simpson adroitly answered the religious objections to chloroform by saying that God, when he performed the operation of taking one of Adam's ribs out, first put him into a deep sleep such as chloroform produces

Both the Prince of Wales and Prince Alfred were sent by their parents to be tutored by Playfair in Edinburgh When the Prince Consort died prematurely in 1861, Playfair suffered a great personal loss, but such was his reputation by this time that the public demands on him inevitably continued He was asked to organize the Jury Department of the International Exhibition of 1862 His work on royal commissions still went on In 1861 or 1862 he was president on a Royal Commission into the British herring fisheries, which repealed the closed season for herring The finding of the Commission was that the closed season enabled the predators on the herring, such as cod and ling, themselves to multiply They were normally caught with herring as bait, with the result that the absence of such bait during the herring close season resulted in fewer casualties among the cod and ling Playfair estimated that the number of these fish that were as a result not caught would in fact themselves eat more herring than those that were caught by all the fishermen of the United Kingdom

In 1865 he served on the Royal Commission on cattle plague, now known as foot-and-mouth disease Playfair himself suggested the measures that have ever since been accepted, of closing markets in affected districts, stopping all transit of cattle, and slaughtering and burning any suffering from the disease These severe measures resulted in great personal unpopularity for Playfair, but his conviction that he was right carried him through

In 1867 he was again a judge at an international exhibition, this time that in Paris Britain did not do nearly so well in that exhibition as she had done in 1851 Playfair saw his chance to drive home the lessons that he had been preaching ever since 1851 He wrote a famous letter to Lord Granville, which the latter asked should be published in *The Times* The following is an extract

"I have just returned from Paris I am sorry to say that, with very few exceptions, a singular accordance of opinion prevailed that our country had shown little inventiveness and made little progress in the peaceful arts of industry since 1862 Deficient representation in some of the industries might have accounted for this judgment against us, but when we find that out of 90 classes there are scarcely a dozen in which pre-eminence is unhesitatingly awarded to us, this plea must be abandoned So far as I could gather them by conversation, the one cause upon which there was most unanimity of conviction is that France, Prussia, Austria, Belgium and Switzerland possess good systems of industrial education for the masters and managers of factories and workshops, and that England possesses none A second cause was also generally, though not so universally, admitted, that we had suffered from the want of cordiality between the employers of labour and workmen, engendered by the numerous strikes, and more particularly by that rule of many Trades' Unions, that men shall work upon an average ability, without giving free scope to the skill and ability which they may individually possess"

This letter was one of the factors that later resulted in the appointment of the Royal Commission on scientific instruction of 1871

The House of Commons

In 1867, the Reform Bill was passing through Parliament, and Playfair represented to Gladstone that it should provide for the representation of the Scottish universities Gladstone agreed, and Playfair found himself approached to be a candidate He accepted after some hesitation, and was elected as a Liberal, despite the fact that the University was predominantly Conservative So far as he could, Playfair stood aside from party politics For the first year or so he decided to learn the business of the House of Commons without making any speeches His first speech was in fact made in 1869, and was in support of the abolition of religious tests in the English universities In this matter, he held that the Scottish universities, which had long before abandoned such tests, were well in advance of those in England In 1870, his attention was switched to matters of postage, when he successfully carried through the introduction of the postcard

Education was a very topical subject at that time, and Playfair was naturally called on to speak on many occasions Irish problems were continually before Parliament, and one of the Bills was that for opening Trinity College, Dublin, to Roman Catholics Playfair, with his liberal views on religion, was a strong supporter of the Bill It was ultimately defeated, because it was likely to interfere with a larger scheme being contemplated by Gladstone When this latter Bill was introduced, it contained some curious compromises, one of which was to exclude priests from lectures on philosophy and history Playfair opposed such measures on principle, pointing out that they forced the student to be "either a bigot or an infidel" His opposition, against a Bill introduced by his own party, was so effective that he carried the day This caused the Government to resign It will be remembered that Playfair had already played a part in the upheaval in the Conservative Party over the Corn Laws, he now caused a comparable upheaval in the Liberal Party Disraeli, however, could not form a Government, and so the Liberals went back Gladstone's respect for Playfair evidently remained, because he offered Playfair the office of Postmaster-General Playfair was just beginning to enjoy administering this post when, early in 1874, Gladstone's Government came to an end, and a Conservative Government was returned at the election

Education in Science and Technology

Outside Parliament, in 1870 he addressed the Midland Institute in Birmingham on his life-long theme of the inosculation of the arts and science This address was full of his usual good sense, coupled with his flare for humorous illustration In this instance he drew a lesson from the behaviour of the natives of Tahiti, who, when they received a present of iron nails from Captain Cook, very prudently sowed them in the ground in order to raise a crop for the next season

Playfair then made an important series of speeches on educational matters. The first of these, in 1870, was on primary education In this he urged that instruction in experimental science should be more widespread "The pupil", he said, "must be brought in face of the facts through experiment and demonstration. He should pull the plant to pieces and see how it is constructed he must apply with his own hand the magnet to the needle He must see water broken up into its constituent parts and witness the violence with which its elements unite . one of the first lessons he must learn from science is not to trust on authority but to demand proof for each assertion All this is true education, for it draws out faculties of observation, and connects observed facts with the conceptions deduced from them in the course of ages, gives discipline and courage to thought, and teaches a knowledge of scientific method which will serve a lifetime. Nor can such education be begun too early" . "Those who are believers in the teaching of the great Secondary Schools of this country will deem my aspirations to improve Primary Education low and utilitarian Frankly I admit the latter Such a style of education will never realize Lord Brougham's hope that the time may come when every working man in England will read Bacon, but it may contribute to the fulfilment of Cobbett's desire, that the time might come when every man in England could eat bacon"

Also in 1870, he addressed the Philosophical Institution of Edinburgh on technical education He concluded "It is for the United Kingdom to determine whether she desires her history to be that of a country which was raised to the highest place among States by the genius of mighty men, though she lost that position by a blind reliance on the practical empiricism of her people, or whether her future history is to be that of an enlightened nation which, seeing that a general diffusion of science and art is giving to other countries advantages in industrial competition, added this intellectual power to the practical aptitude of her population"

Another of these addresses was that on teaching universities and examining boards, and was primarily directed towards saving Ireland from a system of State examinations at university-level He stood very strongly for the system of each university conducting its own examinations, with a maintenance of standards being ensured by the appointment of external examiners In this, he was surely right

A particularly important speech was that on universities in their relation to professional education, which he made to the St Andrews Graduates' Association in 1873 This contains the passage

"Our Latin and Greek education still goes on, though, for its practical uses, it is as much a survival as the two buttons behind our coats are survivals of the time when the slits and flaps of our ancestral coats had to be buttoned away Their existence survives their utility Medical men no longer write or speak Latin and yet a fourth of a professional man's life is spent in the venerable deception that it is indispensable to him . If liberal culture be, as it should be, a part of professional training, then the culture should be made to bear directly on the training, and not remain a mere survival of an education that is only known to us in history New professions are arising around, but for these our old universities make no provisions, and old professions have completely changed their aspects, yet the schools and colleges remain as of old Perhaps the most robust men of our time have been our engineers and mechanicians, for they have given more impulse to civilization than any other class of men. But I look in vain for a single representative man among our Telfords, Watts, Stephensons, Arkwrights, Wedgwoods, whose intellect was nurtured on ancient classical learning, or who could find anything in school life to aid the development of their genius . . If liberal culture be, as it should be, a part of professional training, then the culture should be made to bear directly on the training, and not remain a mere survival of an educational condition that is only known to us in history . And yet our Prime Minister, Mr Gladstone, and Home Secretary, Mr Bruce, make orations on the same day, telling us that the old classical system is that which is best fitted for mental culture, under all conditions "

Reviewing the results of all his efforts for technical education, Playfair in the late 'eighteen-eighties could point to promising progress "I now feel that this work may be left to younger men, but I hope that they will not take their hands from the plough till England has adapted its system of education to the changed condition of competition."

The 'Playfair Scheme'

The fall of the Liberals and the advent of a Conservative Government in 1874 did not reduce official demands on Playfair's time Disraeli asked him to be chairman of a Commission to reorganize the Civil Service This Commission reported in 1875, and was the origin of the 'Playfair Scheme' which divided the Civil Service into two divisions, the upper of which was to be recruited by highly competitive examination at university-level, and the lower of which was primarily clerical This made Playfair extremely unpopular with the clerical side, but his scheme has essentially survived to the present time

Deputy Speaker

In 1876 Playfair was on another Royal Commission, this time on the Scottish universities.

When the Liberals returned to power in 1880, Playfair was offered the post of Chief Whip; but he did not feel adapted for this kind of duty, and so he declined He did, however, accept the office of Chairman and Deputy Speaker of the House of Commons, and this led to the most troubled period of his career It was, in any event, a remarkable post for any man of science to fill, but in addition, it happened that this particular time was about the stormiest in Britain's entire history of Parliamentary Government The basic trouble was the unsatisfactory state of affairs in Ireland, which led the Irish members into a policy of concerted obstruction to all parliamentary procedure It was an extremely difficult time for the Speaker It was even more difficult for Playfair, who had to deputize for the Speaker, frequently long into the next day, but without quite having all that authority which the Speaker by tradition possessed, and in the face of deliberate Irish tactics directed towards exhausting whoever was in the chair There were rules for dealing with obstruction in Parliament, but these had hitherto applied only to individual members It became necessary to extend them to cases of members acting in concert, and during 1881 the Speaker himself suspended twenty-eight Irish members *en bloc* In July 1882, Playfair was in the chair when after nineteen hours' debate on a single clause of one Bill, leading men of both parties pressed him to close the discussion by suspending the obstructing members After detailed warnings, Playfair then suspended sixteen members This action inexplicably brought widespread criticism, even though he had acted strictly according to procedure Some thought that he had been too lenient, others too strict, probably everyone concerned was very much out of temper with the way things had been going, and irrationally blamed Playfair as the man in control, even though the sanctions that he had at his disposal were quite inadequate for the task Playfair was very unhappy, and resigned shortly afterwards It is perhaps possible that someone with a very strong personality might have been able to exert a greater control than Playfair The ability to control unruly audiences seems to require some indefinable personal quality Playfair, when dealing with the rioters in Lancashire, showed that he had this quality to an unusual degree, and if he was unable to control Parliament in these particular circumstances, it is most likely that most other men would have fared even worse In any event, the incident made such an impression that the circumstances were never repeated, in fact, the men who were afterwards most enthusiastic about Playfair's patience and impartiality were the very Irish members whom he had suspended

Despite his retirement as chairman, he continued to be active in Parliament In 1883 he successfully repelled a determined attack on the Act regarding vivisection, which had been carried through Parliament by him in 1876 This Act brought vivisection under control, and made it a condition that no animal should be the subject of a painful experiment without having been previously anæsthetized The opponents of the Act wished to ban vivisection altogether, but Playfair's powerful defence, on the grounds of the value of controlled vivisection to mankind, entirely saved the Act Another attack, also in 1883, was on compulsory vaccination, here the Government were so worried about the outcome that the Cabinet decided to make the matter one for an open vote Here again, Playfair's rational defence of compulsory vaccination was so much more convincing than the emotional arguments of his adversaries that he carried the vote with an overwhelming majority despite the original misgivings of the Cabinet

Playfair was elected president of the British Association for 1885, and took as the subject of his Presidential Address "Science and the State" For an appreciation of this address, see *Nature*, **200**, 7, 1963

Towards the end of Gladstone's second Government, in 1885, Playfair became aware that Gladstone intended to introduce a Bill creating a Minister for Scotland Playfair, who was proud of the record of Scottish education, was against the separation of Scottish affairs under a separate Minister His opposition was all the greater because this would involve the severance of English from Scottish education "This I highly disapprove", he said, "as I think it will be ruinous to Scotch education" His point appears not to have been so much any beneficial effect on Scottish education that might be gained by following an English example, as the fact that attempts might be made in Parliament to bring the Scottish pattern more into line with that in England if Parliament felt that the Scottish differences were being protected by a Scottish Secretary This may appear paradoxical, but Playfair presumably had much parliamentary experience behind his views

Vice-president of the Council

Playfair evidently felt very strongly on the matter, because he decided not to stand as a Liberal candidate for the Scottish universities again, since he felt that even his Liberal supporters were not united on this important educational point Instead, he stood, still as a Liberal candidate, for South Leeds, which was predominantly a working district The Liberals suffered a setback generally in the election, but Playfair himself fought a very successful campaign He appears to have addressed the working men practically as his intellectual equals, and they appreciated it Gladstone, when forming his third Government in early 1886, offered Playfair the post of vice-president of the Council, the holder of this post was effectively the Minister of Education In this office, Playfair carried through a Bill for the reform of the medical profession which gave, incidentally, direct representation to the great body of medical practitioners on the General Medical Council Gladstone's Government fell in 1886 again, on the Home Rule Bill for Ireland On this issue Playfair firmly supported Gladstone in his belief that home rule ought to be given Playfair himself was again returned for South Leeds, but the Conservatives came into office under Lord Salisbury

Celebrations

The following year was the Golden Jubilee of Queen Victoria; Playfair, as a Privy Councillor, witnessed much of the proceedings In 1887 there was also a major celebration of the Declaration of Independence in Philadelphia, the Americans were anxious to have Britain represented at their celebrations in Philadelphia, and they invited Gladstone and John Bright Neither of these men could go, and so Playfair went as the representative of the United Kingdom As we would expect, Playfair's speech was excellently fitted to the occasion He had to reply to the toast of "England, our Mother Home" The speech is too substantial to report at length He replied, he said, "With confidence, because England and the United States now know that they are the chief guardians of political liberty and constitutional Government throughout the world, and that they ought to be linked for ever more by the bonds of friendship and kinsmanship"

Later, on the same visit to the United States, he had the duty of presenting to President Cleveland a memorial in favour of a treaty of arbitration between Great Britain and the United States, signed by 233 members of the House of Commons, and originally prompted by the Peace Society of Working Men

At home, Playfair's measures were as practical as ever. In the same year, 1887, he carried through a Bill which for the first time legalized the sale of margarine as a substitute for butter

There was an election in 1892, which resulted in the return of the Liberals, Playfair again won South Leeds Gladstone, himself an octogenarian, had regretfully decided that he would have, in the face of public opinion, to shed some of the older of his colleagues, he therefore did not invite Playfair back to office, but offered him a peerage as a mark of appreciation Playfair accepted, and became Baron Playfair of St Andrews Even though he was now seventy-four, his public work continued He was appointed a Lord-in-Waiting to the Queen He had to refuse the chairmanship of several further Commissions, because his time was already full with the Aged Poor Commission, and with the work of the 1851 Commission

Tension with the United States

In 1895, Playfair's good relations with the United States were put to a severe test At that time, there was a border dispute between Venezuela and British Guiana In the disputed area which both countries claimed, the Venezuelans had granted concessions to various United States nationals As a result, the United States was drawn into the dispute, and President Cleveland, the same President to whom Playfair had only a few years before carried the Memorial of Arbitration, issued what was in effect an ultimatum to Britain He announced that he himself would set up a Commission and impose its solution on Britain, if necessary by force of arms This outburst, which appears to have been quite unwarranted, produced a severe shock Feeling both in the United States and in Britain mounted towards the stage where war might break out In these circumstances, Joseph Chamberlain, the Foreign Secretary, appealed to Playfair to act as intermediary This was a telling compliment to a man who was at an age normally beyond that of active politics, and who was not of the same party as the Government in power Playfair opened up a channel of contact through the American Ambassador in London, with whom he was on good terms Feeling on both sides accordingly relaxed, and Chamberlain was later able to take over the personal contact made by Playfair, and ultimately a friendly solution was reached, in which the official arbitration confirmed the British claims

The 1851 Exhibition Scholarships

In 1890 Playfair's work with the Royal Commission of 1851 produced another result of lasting value Working on a scheme drawn up by Sir Norman Lockyer [first editor of *Nature*], Playfair's committee proposed to introduce a scheme of scholarships to be supported out of the remaining profits of the Exhibition Writing of this scheme, on his retirement from the office of chairman of the Science Scholarships' Committee in 1896, he emphasized the prospective benefits that these might bring "Suppose, for instance", he said, "by this system one great discoverer like Faraday or Stephenson were to appear among the young scholars thus encouraged by £150 annual grants, a gift would have been presented to this country which would have been cheap had the nation contributed a million sterling to his production" Even while he was writing, this prospect was being fulfilled for in 1895 one of the scholars so appointed was Rutherford Since that time, the record of the 1851 Exhibition Scholars has been one of the most remarkable in science

The Victoria and Albert Museum

The 1851 Scholarships were not quite the last mark that Playfair left on the welfare of Britain In the Diamond Jubilee Celebrations of 1897, there were many projects suggested as the best way of commemorating it Having first ascertained that the Queen was favourably inclined, he wrote to *The Times* suggesting that one last aspect of the 1851 Exhibition had not yet been fulfilled This was to set up a fitting and permanent museum in South Kensington to house the science and art collections inaugurated by the Exhibition itself Playfair had chosen the right moment to strike, and his letter produced a general response Parliament was induced to grant £800,000, and on May 17, 1899, the Queen laid the foundation stone of the new building, henceforth known as the Victoria and Albert Museum

Epilogue

But before this came about, Lyon Playfair had quietly died on May 29, 1898, eight days after his eightieth birthday. The place that he had made for himself in his country's service has never since been quite filled For although a few other men of science have played important and distinguished parts in Government, and although we are thinking earnestly about the part of science in Government to-day, no man of science other than Playfair has risen through regular political means to a position of public responsibility such as he had

It may be worth remarking here that Playfair might never have been in Parliament had it not been for the creation of the Scottish university seats, he might thus have been lost to Parliament had he lived to-day When we recall the distinguished service that he himself and others gave through entering Parliament in this way, we may well regret the abolition of the university seats in the British Parliament If it is considered undemocratic to give university graduates two votes, could we not re-establish the university seats, and give each graduate the option of using either his university or his residential vote ? In this way, we would make it easier for men to follow Playfair's example of transition from academic to parliamentary life, without offending the most doctrinaire democracy

Playfair's own notes about his life were written, he said, partly "that they may form some encouragement to others who, like myself, have had in early life few friends and no influence, to believe that their future position depends upon themselves, and not upon their surroundings" That he had great ability in science is obvious from the attitude of Faraday and other men of science towards him, he could, had he been less interested in humanity, have continued in a happy and distinguished research career But the humane personality that enabled him "to walk with kings nor lose the common touch", equally at ease either discussing the 1851 Exhibition with the Prince Consort or parleying with the rioters of Lancashire, led him to the view that science in isolation was not enough Although he longed for the laboratory, his sense of public service led him on to one Royal Commission and enquiry after another Universities, schools, margarine, postcards, vivisection, vaccination, water supplies, Buckingham Palace, herring fisheries, mine explosions, coal for the Navy, cattle plague, the Civil Service, the 1851 Exhibition, sanitation, famine in Ireland, the aged poor all these and others he tackled with energy, humanity, insight and common sense Invited arbitrator between men and management in the mines, he stood in the gap at a critical time between his own country and the United States

He was not the only man of his time to see what science and technology could do for civilization, nor was he the first He may be held fortunate to have encountered great men like Peel and Prince Albert, who recognized his own greatness early enough for his qualities to be used to the full in his country's service He himself modestly characterized the Playfairs as following "occupations requiring solid, but not brilliant brain power" But he had far more than that He broke through all the barriers of learning, society and politics to take a unique place in British history, and he used to the utmost the opportunities that he thereby earned for the advancement of science and the welfare of humanity. What he did has in many ways made better the fortunes of each one of us to-day What he stood for, a century ago, is still a fresh inspiration

INVESTIGATION OF NON-RECURRING PHENOMENA

THE RESEARCH CINEMA FILM

By E. R. SORENSON and DR. D. C. GAJDUSEK

National Institute of Neurological Diseases and Blindness, National Institutes of Health, Bethesda, Maryland

APERIODICITY is often a matter of crucial interest and concern to science Investigators in many disciplines, faced with the fact of non-recurrence, or their inability to recreate phenomena in which they are interested, are confronted with the problem of recording, preserving, and retrieving data on non-reproducible events for future study The astronomer studying unique celestrial events, the physicist turning his attention to the dynamics of Brownian movement, and the biologist happening on anomalous or passing speciation are no less concerned with the data of such events than the physician investigating individual patients or new diseases, the anthropologist investigating disappearing cultures, and the historian trying to reconstruct the past Similarly, the analysis of the flight of a costly rocket or satellite, or the critical testing of machines and structures to their breaking point, often pose problems which, because of expense in time, effort, and materials, are often best treated as though they were non-reproducible In our own work on the programming of the human nervous system of unique subjects, we often wish to review brief episodes of the programming process which cannot be fully re-created[1-3]

Essential to retrospective investigation of such events is an accessible, reliable record from which data of the original, not to be repeated, occurrence can be preserved and retrieved to re-create, in part at least, the lost phenomenon We have, therefore, turned to two potent recording tools, the motion picture camera and sound recorder, to devise a method of preparing such records, where light and sound recording are applicable Although the desirability of such preservation of original exposed film has been obvious to many, the cost, time, and urge to edit have repeatedly resulted in irredeemable loss of valuable data, through disorganization of reel and sequence identification, derangement of the original time sequence, and discarded footage We suggest here the possibility of avoiding these difficulties and of maximally preserving the basic data in the original filmed record for future investigative use We are reporting elsewhere the detailed method of handling raw footage to create the research cinema film[4]

Data from Non-recurring Phenomena

That preserved data from non-recurring phenomena cannot serve in lieu of the actual events for rigorous scientific study is obvious Neither manipulation of variables nor experimental verification is possible Yet, historical records have often been a vital source material for otherwise unobtainable data on past events and have served to initiate new avenues to scientific enquiry Hypotheses and ideas derived from such survey of historical records may direct systematization of observations and the discovery of new relationships, they may determine the course of experimentation, and their further elaboration may then proceed hand in hand with the controlled laboratory investigations Darwin's observations and impressions during the voyage of *The Beagle* inspired his theory, a concept making possible more definitive investigations By reference to accumulated records of past observed positions of the Sun and planets, Copernicus made his discoveries Similarly, perusal of records personally collected or held by libraries, archives, or museums provides the basis from which theoretical constructs and methods of their validation emerge in such diverse subjects as astronomy, geology, archæology, palæontology, ecology, anthropology, medicine, etc In particular, original tacks and new directions in experimental investigation can be the result of perusal and reflexion on a mass of accumulated data of the past In astronomy, accurate historical records of celestial observations, carefully identified in time and place, are the material *sine qua non* for inspiring and testing many theories Only the accumulation of a mass of such records for study permitted the discovery of the underlying periodicity in many celestial phenomena and the amassing of the body of interrelated data now comprising astronomy The inception of the theory of relativity ultimately depended on this same record

The lyophilized or frozen storage of microbial strains from past epidemics provide living tools for the study of virulence, pathogenicity, and other genetic traits Once these are lost, they are as definitive a loss as the extinction of species of higher animals One may affirm that the preservation of the virus responsible for the 1918 influenza pandemic or that of the infectious disease antecedent to von Ecconomo's encephalitis in Europe in 1918–20 would have been a more valuable contribution to modern knowledge than any examination of the agent performed then or in the interval Sero-epidemiological studies supplying the data for charting, investigating, and predicting disease patterns make use of a file of blood sera which cannot be reproduced by re-bleeding the populations in question at a later date The value of the serum file increases with time, the more so with increasingly accurate and detailed documentation of the subjects and their ecological setting. Uses not envisaged at the time of collection become possible with technical advances in the laboratory

Specific antigens, such as blood group antigens from mummies, may be identified in properly preserved dried or frozen biological materials Pollen grains may be identified in lake sediments or burial remains, and examination of ancient bones and teeth can reveal much about the nutrition, diet, and disease patterns of ancient peoples Thus, archæology, palæontology, and anthropology draw on records of excavations, explorations, and labelled museum collections without which much of our knowledge of the development and evolution of life and man would not be possible

Much of linguistic science depends on historical records of contacts and shifts of peoples, and on the written records of languages no longer spoken If most of the writings of the Mayas had not been destroyed by the zealous *conquistadores* and, instead, had been preserved, we would very likely long ago have been able fully to decipher the Mayaglyphs, with all the implications to the studies of linguistics, anthropology, and the human mind which the unravelling of this apparently independently originated written language would entail

Stored materials most useful are those which permit new analysis or measurement of specimens or re-analysis of data from the past The collections of libraries, archives, and museums provide much of the material needed for such investigation, and from them it is possible to create sufficiently precise new theoretical constructs to suggest further methods of validation, as in the use of dendrochronology or carbon-dating to verify the age of objects in museums or *in situ*

The Research Cinema Film

In our effort to record the language, movement, and other actions of children in primitive cultures, and the influences which determine this behaviour, we turned to the motion picture camera and sound recorder to capture and preserve data for later study We needed a method to permit review of brief episodes in the programming of the human nervous system and to provide data for the delineation of the various cultural and environmental forces producing this programming We have been very concerned with preservation of information on child development available from the now rapidly disappearing unique, isolated, and divergent primitive cultures, a concern confronting us dramatically with unreproducible events and non-recurring phenomena Our methods of handling cinema records are, however, applicable broadly[3,5]

From entertaining a fantasy of having cinema records from the travels of Xenophon, Marco Polo, Cortez, Captain Cook, and Darwin, among others, we have come to realize that we would want, in addition to the photographic records, extensive documentation of other kinds, such as associated field reports, journals, diaries, logs, tape-recordings, maps, studies, specimens, or other pictures Furthermore, we would like to have a way to relate the films to other occurrences and their preserved records The most convenient way to do this is by time, place, and subject identification, the precision of which largely determines the extent to which the filmed record can be related within itself and to other records We would certainly want to have preserved all the cinema footage exposed, rather than that selected and edited according to the interests or tastes of the time, and we would want to know what interests governed the use of the camera The names of the filmers of each section of the research film are also important, so that their filming habits can be recognized and taken into consideration when attempting to evaluate the filmed record

Film, more easily than most other types of records, can become the source of information and observation unforeseen by the filmer The camera, even when aimed at specifically chosen material, invariably picks up, unapprehended and unanticipated, incidental surrounding information which we may neither understand nor recognize at the time Review of such data can be the basis for uncategorized, intuitive impressions supplying the clues to fruitful avenues of enquiry Fleeting situations can be captured on film for leisurely review at a more propitious time, the speed of motion of the photographic record can be modified as needed, as in time-lapse photography or high-speed motion pictures, and random use of the camera can yield records of information which we have not yet attempted to apperceive, recognize, or evaluate

Fig 1 Flow chart showing steps in preparation of research films

In order to exploit fully these virtues of the camera, we have developed the research film as a cinema record of discrete occurrences, cross-filed with related data, in which the original time sequence of the filming has not been disrupted or altered, the subject-matter of concern to the filmer has been identified in time, place, and person, and the professional bias and interests of the filmer and sponsor have been indicated

Technique for Research Film Production The beginning and end of each film are governed by the nature of the subject and the amount of film taken Large amounts of footage from a single time and place related study or survey are divided into parts not more than 1,600 ft in length (in the case of 16-mm film), for the sake of convenient storage, and natural divisions are used as much as possible in determining the beginning and end of each part The original exposed reels of film are developed, spliced together, and copied in a work print The work print is reviewed to check the accuracy of order, and technically unusable footage, such as that unexposed, totally light struck, or decomposed, is cut out.

The main title of the film includes the name of the event or subject under study, precise and detailed geographic identification, the purpose of the filming, and the dates or times covered by the film. Preliminary credit titles show the disciplinary bias, names of filmers, and sponsorship. Major subdivisions of the research film are indicated by appropriate titles which signal changes in time, place, or subject sought by the filmer; they are determined by the filmer while reviewing the work print, on which he marks their intended locations. When these titles have been composed and photographed, the work print is used as a guide for inserting them into the original footage.

Unusable footage, previously cut out of the work print, is also removed from the original, and corrections in time sequence are made, in the event that some sections were inadvertently out of order. A projection print is copied from the trimmed and titled original, and a magnetic recording stripe is put on to one edge. The original research film is then permanently filed in a film storage vault, and the copy for viewing is placed in a research film archive, after the filmer has narrated comments from memory or notes or transferred any synchronously recorded field sound on to its magnetic sound stripe.

Information giving background to, or revealing influences affecting, the behaviour of the specifically pictured subject are recorded on the sound track. The sound track may also serve to alert the viewer to imminent material which may otherwise pass before notice can be made. Unusual names or terms mentioned in the sound track also appear in the titles. Maximum identification is sought, and, whenever the identifying material is too long to be handled in titles or the sound track time is too brief to contain the needed additional information, appended typescripts or charts are keyed to the appropriate sections of the film by reference to the title covering the section or, when necessary, more precisely by the edge or frame numbers. In accompanying note-books, field journals, or logs, data relating to the filming and the subject-matter are preserved at greater length, and the interests guiding the camera are further revealed.

Special Films. One of the important uses of the research films will be to provide the material for special purpose documentary, scientific, demonstrative, or educational films, without disrupting the original research film document. Indexing and edge-numbering the research film make it possible to select and locate the needed sequences. If the originally made work print has not already been cut and used for such special showing, it may serve as the work print for the planned special film. When the value of the special film is such that many copies are desired, a printing master of the appropriate footage can be made from the original film and assembled with whatever other material might be required. From this printing master the desired number of special film copies can be made.

In the profession of motion pictures we discovered immense pressures stemming from the traditional uses of motion pictures for specific scientific investigation, educational purposes, or for promotion or entertainment, which tended to direct all film endeavours, including those of science, into diversionary, didactic, or documentary productions. The paraphernalia and methods of the industry were organized to demonstrate particular attitudes, beliefs, or desires from specially ordered observation, or to fabricate illusion through the reorganization of realistic, credible images. However, in spite of the greater coherence and smoothness of presentation of carefully edited and reorganized film, it became increasingly clear, as we developed our research film method, that no cutting, rearranging, abstracting, or correlating of scenes from original footage would be permissible in research films and, in particular, the time sequence of the original footage could not be disrupted. The research films were to be neither a summation of information, a demonstration of a conclusion, nor the imposition of an already structured idea or system of knowledge, but rather a source of material for viewers with investigative interests in events of the past. Contrary to the production of usual motion pictures, the work on preparing research films is principally that of extensive identification of subject-matter in its original time sequence and correlation of the filmed data with other associated material.

EVIDENCE FOR LIFE ON MARS

By Dr. D. G. REA

Space Sciences Laboratory, University of California, Berkeley 4

IN 1954, de Vaucouleurs[1] wrote, "As for the idea, so often expressed, of a different kind of life adapted to such conditions (that is, on Mars)—what might be termed a 'generalized life'—it remains to a large extent beyond the realm of positive science".

This approach does not seem to have had much appeal, and most authors since then have stressed the positive aspects, generally overlooking contradictory observations. Indeed, the reader would undoubtedly conclude that various observations of Mars indicate considerably better than an even chance for the existence of life there. My opinion is that the evidence has been distorted and that a re-examination is required. An examination of the scope necessary will not be undertaken here, rather only a few observations intended to illustrate this point will be presented.

The observational arguments for the existence of Martian life are (1) the various colours, including green, exhibited by the dark areas; (2) the seasonal changes in the visual albedo and polarization of the dark areas; (3) the ability of the dark areas to regenerate after an extensive 'dust storm'; (4) the presence of 2,700–3,000 cm^{-1} 'absorption' bands, attributed to organic molecules.

It has been shown recently that the last, most recent, point is at least doubtful[2]. The argument on the basis of the colours is also inconclusive. Kuiper[3] demonstrated the absence of the near infra-red reflexion maximum, characteristic of most green plants, indicating that chlorophyll was not responsible for the colour. In this context Sinton has noted that this does not exclude chlorophyll since there may be present other pigments absorbing the near infra-red radiation. This would actually be expected since any Martian plants would probably evolve into forms reflecting the barest minimum of the sparse solar radiation available. It has been suggested by many workers that the colour is a contrast effect with the bright reddish continents The meagre quantitative data have been discussed by Öpik[4], who has reduced photometric observations of Kozyrev on the very dark area Syrtis Major to intrinsic reflectivities by factoring out the estimated atmospheric attenuation and reflectivity.

The result is that this area is bluer than a continent, but its colour is still reddish His reduction is questionable since he assumes the surface-scattering properties to be similar to the Moon in the sense that the disk would be uniformly bright if no atmosphere were present In fact, quantitative studies by Dollfus[5] show the surface to have reflecting properties in orange light intermediate between lunar and Lambert surfaces However, the qualitative conclusion that Syrtis Major has a red tint seems reasonable While these considerations all weigh against a chlorophyll-based plant life, the lichen systems suggested by Kuiper (but criticized by Salisbury) can satisfy the observed colours, real or imaginary The broad-leaved plants envisaged by Salisbury must have a chemical composition completely unlike any such terrestrial species, but this is to be expected The significant point is that there is no positive colorimetric evidence pointing to forms of vegetation with which we are familiar

The second and third arguments remain the most cogent, but the second loses some of its allure when one considers the severity of the Martian climate Focas[6] has photometered several dark regions on Mars from plates taken over a Martian year All reveal a seasonal change in the albedo with a distinct darkening wave moving from pole to pole with the seasons An area showing one of the greatest seasonal changes is Depressio Hellespontica, located at about 60°–65° S latitude Now the temperature at this location, according to the data of Lampland as reduced by Gifford[7], reaches a maximum of –23° C for the southern summer This temperature has an uncertainty due, among other factors, to the assumptions that the surface radiates as a black-body and the atmosphere is transparent The latter is reasonably valid for the 8–13-μ terrestrial window used for the observations, but the first has been questioned by Öpik, who believes the emissivity to be closer to 0 75 than to 1," by analogy with terrestrial substances" The net effect is to raise the Martian temperatures by about 5 per cent, that is, about 13° C, making the environment more hospitable to life Actually there are few data in the literature on the emissivity of terrestrial surfaces, but at least one report[8] indicates that the emissivities are higher Even accepting this low emissivity and possible systematic errors, it seems unlikely that the summer temperature of Depressio Hellespontica could be raised to 0° C Accepting this, and knowing the uninviting composition of the atmosphere, it appears highly improbable that any life, based on water as solvent, can exist in this region with the activity necessary to explain the darkening variations Schemes can no doubt be envisaged to circumvent these objections, but they must surely be very special If a non-life mechanism must be invoked to explain the seasonal change of the albedo for this one dark area, it is reasonable to assume it is applicable to the other dark regions and that this property cannot be used as an indication of life, even at the equator where the temperatures are more equable

Together with the seasonal change in the albedo a concurrent variation in the visual polarization has been observed by Dollfus[9–11] For the autumn and winter seasons in a particular hemisphere the polarization of the corresponding dark areas has a negative minimum of about –0 012 at a phase angle of 11°, and then increases with a value of 0 0 occurring at 25° In the spring and summer the dependence of the polarization on phase angle changes so that for the maximum difference, in late spring, the minimum polarization is –0 015 at a phase angle of 13°, and the zero point occurs at a phase angle of 30° The shift in the polarization curve cannot be due to atmospheric effects but must arise from changes in the surface Dollfus says this must be a change in the surface texture which in turn is most likely due to the proliferation of highly coloured micro-organisms when the water vapour from the subliming polar cap reaches a particular area Attempts to duplicate the Martian behaviour using terrestrial biological samples on inorganic substrata were unsuccessful, but this is not a strong counter argument since life-forms are highly adaptable and would presumably differ on Mars from terrestrial ones

However, there does not seem to be justification for relying so heavily on a life interpretation If the argument on the seasonal albedo variation is accepted then presumably an inorganic interpretation must also be found for the polarization variation Two possibilities based on the very extensive laboratory work of Dollfus[12] can be suggested First, it is not necessary to invoke a change of texture to explain the change in the polarization curve If the surface material becomes more absorbing in the spring then both the albedo and polarization will change in the manner observed Although no suitable mechanisms have been proposed to produce this darkening, the possibility should not be overlooked Secondly, a change in surface texture in which the surface becomes rougher will also explain the data Dollfus has demonstrated such a difference between samples consisting of the same small particles but where one has a smoothed surface and the other a surface roughened by stirring He concludes that the agglomeration of particles into larger entities increases the multiple reflexion of light in the surface and shifts the polarization curve In the case of Mars, the surface could be roughened by the removal of small loose particles by appropriate winds The material remaining would then be small particles partially cemented together into larger particles, perhaps similar to the "fairy castles" of Hapke and van Horn[13]

The rejuvenation property of the dark areas is one aspect which can be basically accepted as pertinent, although, as Salisbury has pointed out, a lichen cover would not be expected to behave in this manner Higher forms of plant life such as Salisbury favours would possess this property

While certain observations seem to favour life, others are very difficult to explain by this hypothesis The normally bright region Hellas was dark during the 1954 opposition but returned in 1956 to its position as the second brightest area on the planet, only the polar caps exceeding it in reflectivity[14,15]. Any form of plant life which, under Martian conditions, can so rapidly expand over and then retreat from an area of 290,000 square miles must be truly unique Other non-seasonal changes in the extent of the dark and bright areas are equally difficult to explain by a life hypothesis

As an alternative to the interpretation of life on Mars, I prefer an inorganic explanation based on ideas of McLaughlin[15] and Kuiper[16] Assuming volcanoes, both active and dead, and suitable winds, the phenomena can be interpreted in a reasonably consistent manner Thus the temporary darkening of Hellas would be ascribed to a film of volcanic ash produced by an active volcano just prior to the 1954 observations This volcano then became passive and the winds proceeded to scour the area (McLaughlin considers it to be a high plateau since "it is often snow-covered, and in winter forms a vast extension of the polar cap down to latitude 30°"), restoring it to its previous brightness Other non-periodic changes would be explained in like manner, involving appropriate combinations of volcanic ash, lava and winds

The regenerative feature according to Kuiper is then achieved by atmospheric circulation Presumably this involves dust being blown on to the dark areas (postulated by Kuiper to be lava and not ash) during the late summer, autumn and winter, and then removed during the spring Öpik objects to such an interpretation, his principal argument being that radiometric and polarimetric measurements indicate that "the soil of the dark areas seems to be of the same grainy nature as that of the bright areas" This is not convincing, since volcanic lava can have optical and thermal properties which are not dissimilar to those of the dark areas—similarity of certain optical and thermal properties for two materials does not guarantee that they are of the same nature Öpik also states that the presence of life is indicated by the permanence of the dark markings in spite of the numerous extensive dust storms. Without a regenerative property "during millions of centuries the dust storms would have covered the entire planet with a deep layer of dust " The significance of this statement is decreased by his acceptance of a surface which has a non-uniform elevation (also see Dollfus[14]) This is intended not as a complete treatment of the volcanic-wind model but as an indication of its real possibilities I am inclined to favour it, although not rejecting the interpretation of life on Mars

The question of life on Mars has intrigued scientists for decades Owing to the possibility of being able to verify directly the life hypothesis in the very near future it is becoming a subject of widespread study One approach is to determine if certain terrestrial organisms can exist, perhaps in a modified form, in the Martian environment Workers in this field have been encouraged by the recent positive identification of water vapour in the Martian atmosphere[17,18] The second approach is to investigate whether the various observed Martian phenomena suggest that life exists there. It is to this area that the present article is addressed On the basis of this brief discussion it is suggested that the life interpretation is very tenuous and that inorganic interpretations be given greater credence

PROPOSAL FOR AN EDUCATIONAL RESEARCH COUNCIL AND SOME OF ITS IMPLICATIONS

By PROF R. D'AETH
Department of Education, University of Exeter

THE recent submission to the Minister for Science of a proposal for an Educational Research Council raises important questions about the future development of research in education, and also indirectly about the future relationships of research councils with the Government The memorandum making the proposal, which was supported by the Heads of Departments and Institutes of Education of the Universities of England and Wales, calls for a council with responsibilities similar to the three long-established research councils It is evident that the proposal will have to be considered on its own merits, and also as part of a movement to persuade the Government to provide money on a broader front for research of national importance

The Medical Research Council dates back to 1913, the Department of Scientific and Industrial Research to 1916, and the Agricultural Research Council to 1931 What is striking is that since then, in a period of more than thirty years, the only addition has been the Nature Conservancy Yet during this period there has been a growing appreciation of the need for more research in fields of national importance The budgets of the three large research councils have increased enormously, and there has been increasing pressure, especially in recent years, on the Government to give more support to research in education, and in economics and the social sciences generally

The three large research councils were started at the time of the First World War and of the subsequent severe economic depression The vital importance of scientific research was demonstrated even more sharply in the Second World War Since then, in two decades of intense economic competition, scientific research has proved to be just as crucial for the nation's survival and progress But there has been one very significant new realization that for the nation's prosperity it is equally important to develop its resources of human skill and vigour to the fullest possible extent Sir Eric Ashby, this year's president of the British Association, highlighted this point of view in his address when he made a searching analysis of Britain's "Investment in Man" at the level of higher education (*Nature*, 199, 877, 1963) In it he pointed out that, although more than £70 million a year is spent on universities, the expenditure on studying the process of teaching and learning in them is negligible Overall he estimated that expenditure on research in education is less than 1/20 of a penny in every pound spent on education This agrees with other estimates which have similarly put expenditure on educational research at about 0 02 per cent of expenditure on education. This would lead to rapid bankruptcy in most enterprises and education has become a large-scale enterprise on which the Government alone spent more than £1,000 million last year, far more than on any other public service except defence The consequence of this neglect of research is that decisions involving the expenditure of millions of pounds, and affecting the lives of generations of young people, are often taken on fragmentary evidence, or policy is shaped by a committee lacking information, or outmoded ways are carried on through engrained custom

Here the question naturally arises To what extent are educational problems susceptible to research of a scientific kind? Are not value judgments commonly involved? The answer is certainly that they are, and that a scientific approach cannot embrace education as a whole, even when the scope of this elastic word is restricted to the influences of 'organized' education, or of educational institutions, on children growing up But it is equally true that many aspects of education can be studied scientifically, as a few examples will show. For example, there has been much scientific research on the preparation of standardized mental tests for diagnosis, selection or measuring attainment Again, the psychological study of infants and young children has already cast rays of light into their mental growth and how they learn Or to take a more specific example, scientific research has transformed the teaching of deaf children Many more examples could be given, yet each of them brings to mind many associated problems which await investigation, and often projects have to be started empirically because there has been no underlying theoretical research The map of educational research is largely uncharted, not because of difficulty over techniques—it is significant that a number of research projects started in the past five years with grants from Foundations have begun to yield results quickly—but through lack of money and skilled research workers

Let us turn back, however, to the question of 'value judgments' for a moment They are inherent in educational thinking overall and there are obvious dangers if such things as '11 + tests', however admirable scientifically, are seen too much in isolation It is salutary also to remember that scientists cannot exclude 'value judgments' from their research, and are often entangled by it over the applications of research Are birth control, abortion, euthanasia morally right? Should the scientist whose research develops nuclear bombs feel any responsibility over their possible use ?

The growing realization of the need for more educational research has already led to more money being made available The Nuffield and other Foundations have given grants for a number of projects, and the Ministry of Education has also been able to make grants for research during the past two years Two of the new universities are going to study teaching at university-level, and the Robbins Committee is likely to stress the need for more educational research in its forthcoming report on the development of higher education The amounts of money available are still relatively very small, but they could be increased substantially If this were done, what would be the advantages in having an Educational Research Council ? Behind such questions there lurks the natural fear that pressures might lead to other research councils springing up like mushrooms, and this is presumably what the small committee set up by the Government in June, with Lord Heyworth as chairman, will look at, its terms of reference being "To review the research at present being done in the field of social studies in Government Departments, universities and other institutions, and to advise whether changes are needed in the arrangements for supporting and co-ordinating this research" The proposal for an Educational Research Council will no doubt be considered by this Committee in due course In the meantime, however, it is worth looking at the arguments in its favour

The main task of an Educational Research Council would be to encourage and give financial support to research in education, not simply to consider projects submitted by universities and other institutions of learning, but to assess critically the needs and opportunities for research judging the urgent needs of the present, deciding in the light of varied research experience which long-odds ideas or unorthodox investigations should be taken on as risk ventures, looking ahead to problems of the future This means watching the field as a whole, shaping not so much a clear programme as a continually growing strategy, looking not only at educational problems, but also at developments in other fields that might become significant—as has been proved to be necessary in medicine and agriculture and in the application of science to industry The province of the Council should be all of what might be termed 'organized education' not just schools, but also universities, technical colleges, the training of teachers, the use of radio and television and so on, seeing them as interrelated parts of an overall picture

The giving of grants for research projects will soon prove ineffective unless guided by a long-term and developing policy, taking account of both research needs and opportunities and also the training and career prospects of the required specialists It would be necessary to grant enough studentships for training, and also fellowships for the conduct of research, ensuring reasonable career prospects in research while retaining ease of transfer between teaching and research It is these linked functions, exercised over primary, secondary and higher education, which provide the main argument in favour of an Educational Research Council But there is also another aspect which would be important in the long run, namely, the need to keep the planning of research free from the day-to-day control of the executive departments of Government That is why the existing research councils were established under the Lord President of the Privy Council, and retained their independence when transferred in 1959 to the same person in his new capacity as Minister for Science and it was for the same reason that the proposal for an Educational Research Council was submitted to the Minister for Science There is, however, an additional reason in the case of education, in that a number of institutions, including the universities, do not come under the Ministry of Education The most valuable link between the Research Council and the Ministry of Education would be in the application of research findings, and here the Ministry has already taken a very significant step in proposing the formation of a Curriculum and Examinations Council

The nature of the responsibilities of the proposed Research Council, and the need for it to gain the respect —as the three large research councils have—of universities and other institutions of higher education, requires that its members should be of recognized standing, and that the Council should be small enough to be effective in action There would be little need to argue this point among the leaders in industry and commerce But there are sad examples within the sphere of education of committees so large as to be rather incoherent, so representative that they are almost restricted to compromises between set points of view, and which are sometimes only kept alive by the efforts of the chairman and secretary These are weaknesses which the three large research councils have avoided The oldest of them has now been established over half a century, and it is worth considering the reasons for their success They have had direct, not advisory, responsibilities They have had the services of the leading research experts The spheres of activity covered by them—medicine, agriculture and the application of science to industry—have been distinct enough to avoid confusion and overlapping, and they are of acknowledged national importance They have been answerable to the Government in broad terms for the proper discharge of their responsibilities, and not for the details of their programmes These are the conditions which have enabled them to function with vigour and imagination

It is a question for serious thought whether these conditions would apply to a research council for the social sciences, and one with which the Heyworth Committee will obviously be concerned A significant feature of the three large research councils is that the coherence of each comes from its field of application They are not related to single academic disciplines Rather the reverse, for the Medical Research Council is concerned with the various branches of medicine, biochemistry, physiology, bacteriology, psychology, demography, molecular biology and so on Likewise the Agricultural Research Council draws on the various branches of agriculture, botany, zoology, genetics, chemistry, economics and so on The Department of Scientific and Industrial Research also covers a wide academic spectrum An Educational Research Council would have a similar coherence of application, but it is difficult to see how a research council for the social sciences in general could do so

Universities draw Government money for research from two main sources from the University Grants Committee and from the three large research councils. The expenditure of the former was more than £70 million last year, while the budgets of the latter exceeded £30 million. By no means all the latter went to universities or technical colleges, for the three councils run large separate research institutions. Yet the tendency for money going to universities through the University Grants Committee to be closely tied to increased numbers of students makes it more difficult to get money for research, and is unlikely to be reversed. In consequence the research councils have a powerful influence on the development of research in universities, which is related to the policy for dividing advanced scientific research, especially that requiring very expensive equipment, between universities and specialized research institutions. Hence the two main sources from which universities receive money for research exercise quite different influences the University Grants Committee reaches a co-operative agreement on the form of the growth of each university, the three councils plan, in their respective spheres of application, the development of scientific research nationally. If the arguments outlined here carry weight—that there is an important need for more educational research, and that there are several linked functions which should be planned on a national basis—then the claim for an Educational Research Council is strong. The expenditure involved would be very small in comparison with the existing research councils. It would not by itself have any effect on the present situation as regards the importance of scientific research, and the growing expenditure by the Government on it. But these may lead, in any event, to a review of the machinery of Government which would affect the independence and responsibilities of universities, the University Grants Committee and perhaps even the research councils, which have shown how planning on a national basis can be combined with adequate freedom and scope for initiative for those engaged in scientific research.

NEWS and VIEWS

Bacteriology at Glasgow: Prof. R. G. White

Dr. Robert G. White, reader in bacteriology at the London Hospital, has been appointed to the Gardiner chair of bacteriology at the University of Glasgow in succession to Prof. J. W. Howie, who has been appointed director of the Public Health Laboratory Service Board (see *Nature*, 197, 749, 1963). Dr. White was educated at the Queen's College, Oxford, and qualified from the London Hospital Medical College in 1942. He gained his D.M. at Oxford in 1953. After a period of training in bacteriology under Sir Samuel Bedson in the Emergency Medical Service Laboratory at Epping (1943–44) and of supervising the Central Emergency Medical Service Laboratory in the University of Liverpool (1944–45), he spent two years of service with the Royal Navy as a specialist in bacteriology. On his return to the United Kingdom he joined the Department of Bacteriology at the London Hospital, first as registrar in pathology and later as Freedom Research Fellow. He was appointed reader in bacteriology under Prof. C. F. Barwell in 1954. Visits to the United States were made during this period when, in 1952, he spent a year with Dr. A. H. Coons at the Harvard Medical School as a Medical Research Council Travelling Fellow, and in 1961 when he was travelling professor to the University of Florida and worked there with Prof. E. Suter. Dr. White's research interests have been concerned with a wide range of experimental work bearing on such topics as cellular reactions in immunity, the adjuvant activity of mycobacterial peptido-glycolipids, the role of the thymus gland and auto-antibody responses.

The Rensselaer Polytechnic Institute: Prof. J. D. Mackenzie

Dr. J. D. Mackenzie has been appointed to the newly established professorship of materials science at Rensselaer Polytechnic Institute, Troy, New York. The appointment will strengthen the teaching and research of non-metallic solids in the Department of Materials Engineering at Rensselaer. Dr. Mackenzie graduated at Birkbeck College, London, in 1952 with honours in chemistry, and was awarded a Ph.D. and the Diploma of Membership of Imperial College of Science and Technology in physical chemistry by Imperial College of Science and Technology, London, in 1954. He was a Post-doctoral Fellow at Princeton University from 1954 until 1956. In 1956 he was elected to an Imperial Chemical Industries fellowship at Cambridge, and became a Fellow of the Royal Institute of Chemistry in 1958. Since 1957 he has been with the General Electric Research Laboratory, Schenectady, New York.

The Institute of Electrical and Electronics Engineers

A United Kingdom and Eire Section of the Institute of Electrical and Electronics Engineers (IEEE) has been established to serve the interests of the Institute's members in Great Britain and Ireland resulting from the merger of the Institute of Radio Engineers and the American Institute of Electrical Engineers to form the IEEE. The new Institute is a 'non-national' professional society of some 160,000 members, organized in nine Regions and with learned society activities designed to serve the expanding field of electrical and electronics engineering. Membership of the United Kingdom and Eire Section is made up of IEEE members of all grades who are living in Great Britain or Ireland and represents about half the present membership of the European Region of the IEEE, the territory of which is bounded by the Urals and the north coast of Africa and includes other sections in Benelux, Egypt, France, Israel, Italy, Norway and Switzerland.

The officers of the United Kingdom and Eire Section are *Chairman*, Dr. R. C. G. Williams, *Vice-Chairmen*, Sir Harold Bishop and Sir John Hacking, *Treasurer*, Dr. R. L. Smith-Rose, *Secretary*, Mr. F. S. Barton; *Assistant Secretary/Treasurer*, Mr. R. C. Winton. Until the Section Executive Committee is established, its functions are being carried on by the Advisory Committee of the IEEE in the United Kingdom and Eire which acts on behalf of the Board of Directors of the IEEE. The aim of the Section will be to achieve close co-operation with the Institute of Electrical Engineers, the British Institute of Radio Engineers and other professional societies, which between them already hold several hundred meetings, colloquia and conferences a year throughout Great Britain and Ireland covering all aspects of the electrical and electronic field. In these circumstances, the role of the Section will be primarily to join in or initiate joint meetings or conferences, and to carry out the special function of providing a two-way link with professional activities in the United States and elsewhere. In this way more opportunities will be created for lectures and papers by American engineers in Britain and by British engineers in the United States. Further information can be obtained from Mr. J. R. Smith, 2 Savoy Place, London, W.C.2.

British Computer Development Project

The first contract in a four-year £1½ million joint research project, which is planned to aid long-range British computer development, has been agreed between the Department of Scientific and Industrial Research and Mullard Research Laboratories This will extend Mullard's existing programme of research in low-temperature computer devices, and, spreading over two years, will cost a total of £100,000, to which the Department will contribute half The project is designed to support the British computer industry's already considerable research and development efforts in the face of future widespread technological change Twelve major British electronics firms are involved, as well as Government laboratories The National Physical Laboratory at Teddington will act as a co-ordinating centre for the programme as a whole in close association with the Ministry of Aviation's Royal Radar Establishment at Malvern About two-thirds of the total estimated cost will be borne by the Department of Scientific and Industrial Research, the remaining third being provided by those industrial firms which accept contracts About one-third of the total sum will be expended in the National Physical Laboratory and the Royal Radar Establishment, and the remaining £1 million will be spent in industry in the form of development contracts The first contract is concerned with low-temperature computer devices It is known already that superconducting stores are feasible, and, in particular, research will be carried out on one form of superconducting element—the cryotron—as a storage device It is most likely that the cryotron will also be used in the selection circuits of superconductive stores, and in regular arrays of switching circuits such as might occur in stores with special logical properties, sophisticated stores of this type may first become a practical proposition by the use of superconducting techniques The work to be done under the contract has three aspects First, the greater understanding of the physics of the cryotron, secondly, the further development of methods for laying down arrays of film with the desired purity and geometric form, and thirdly, the use of the devices in computer stores.

The Applied Scientific Research Corporation of Thailand

A National Scientific Research Organization is to be set up in Thailand under the leadership of Mr Frank Nicholls, of Melbourne, who has drawn up the plan for mobilizing Thailand's scientific resources to develop the country's industries

Mr Nicholls is international co-operation officer of Commonwealth Scientific and Industrial Research Organization (Australia) He has spent most of the past three years in South-East Asia, mainly investigating the scientific resources of developing countries He was a member of the Science Commission appointed by the President of Pakistan in 1959 to study that country's scientific work He has spent three periods in Thailand preparing the way for the establishment of the Applied Scientific Research Corporation of Thailand, and he drafted the Act recently passed by the Thai National Assembly for that purpose He has now arrived in Bangkok to head the team of some twenty international experts working under the United Nations, which is establishing the Research Corporation on the lines of the Commonwealth Scientific and Industrial Research Organization The Research Corporation of Thailand will be concerned with research in agriculture, industry and health It will examine ways of preparing for the growth of new industry, of supporting existing industries, exploiting mineral resources, finding new uses for plant products, and developing textile and building materials The Thai Government has taken the initiative for setting up the Research Corporation and has already earmarked ample funds for the work of the initial five-year period Aid will also be given from the U.N. Special Fund and several international foundations

Properties and Applications of New Ceramics

A booklet, *New Ways with Ceramics*, issued by the Department of Scientific and Industrial Research and written with the co-operation of the British Ceramic Research Association, outlines the properties and applications of the new and improved ceramics which have been developed to meet special industrial requirements, especially for work at high temperatures (Pp 12 London: Information Division, Department of Scientific and Industrial Research, 1963) Outstanding among these is boron nitride, which is easily machined, impermeable and has excellent electrical and corrosion-resistance properties up to 1,650° C Others described are alumina ceramics, boron carbide, silicon carbide and the cermets, which are complexes of metals and metallic oxides adjusted to bring out desired characteristics.

Bovey Valley Woodlands National Nature Reserve

The Nature Conservancy has declared the Bovey Valley Woodlands a National Nature Reserve One of the earliest National Nature Reserves to be acquired (1952) was Yarner Wood in the Bovey Valley, north-west of Bovey Tracey on the eastern edge of Dartmoor Recent plans for extensive conifer plantations, in some cases replacing scientifically interesting semi-natural woodlands, led the Nature Conservancy to review their Nature Reserve plans and to begin adding a number of further small woodlands to the Yarner nucleus Three such adjoining woodlands, Rudge (36 acres), Woodash and part of Houndtor Wood (61 acres), have been purchased as a step towards forming an enlarged Bovey Valley Woodlands National Nature Reserve within the Dartmoor National Park The upper reaches of the River Bovey between Lustleigh Cleave and the little valley including the well-known Becka Falls contain one of the best remaining series of Dartmoor native hardwoods Rudge Wood occupies one side of the steep slopes at the lower or southern end of the valley and extends through a short succession of wet and boggy fields, carrying much willow, alder and birch, almost to the southern extremity of Houndtor Wood The latter takes in the very steep northern flank of Houndtor Ridge, which shows the geological transition from the Culm through the metamorphosed Culm to the Granite, where it adjoins Woodash Wood Oak is the predominating tree throughout the Reserve, and the two species, pedunculate and sessile, are both well represented Ash is frequent mainly on the damper alluvial sites and also on granite-derived soils The woodlands are rich in the smaller forms of plant life, such as mosses, liverworts and lichens, especially along the river margins, where large strewn boulders and damp shade provide a favourable habitat for them. Access to the Reserve away from the public footpath will be by permit only Applications to visit the Reserve should be addressed to the Regional Officer (South-West), Furzebrook Research Station, Wareham, Dorset

Last Essays of R. E Snodgrass

Over a period of nearly forty years, R E Snodgrass published in the *Smithsonian Miscellaneous Collections* a series of masterly articles on the anatomy of insects At the time of his sudden death in September 1962, at the age of eighty-seven, Snodgrass was engaged in writing a kind of encyclopædia of insect anatomy. About a fifth of this had been completed and has now been edited by Dr A Glenn Richards and published as a final contribution in the *Smithsonian Miscellaneous Collections* under the title "A Contribution Toward an Encyclopedia of Insect Anatomy" (146, No 2 Pp v+48 Publication 4544 Washington, D C Smithsonian Institution, 1963) This was well worth publishing It takes the form of a succession of brief essays on most of the terms used in descriptions of the external anatomy of insects. Snodgrass wrote always a fine style of lucid English. He had a feeling for words, an interest in their etymology, and a gift for clear definitions. All these characteristics are evident in this contribution.

Prof. Eugène Pittard

THE *Bulletin de la Société Suisse d'Anthropologie et d'Ethnologie* for 1962–63 contains an excellent appreciation of the late Prof. Eugène Pittard of Geneva, who died a little while ago, aged ninety-five. Pittard was a delightful individual full of enthusiasm. One always looked forward to meeting him at archæological and anthropological congresses and similar functions. He started out as a zoologist, but soon found that anthropology was his real interest and vocation. He was no narrow specialist; everything concerning man, whether physical or cultural, interested him. Thus when prehistoric archæology blossomed towards the start of the present century Pittard was one of its foremost exponents. The University of Geneva eventually, in 1916, provided him with a professorial chair, and three years later with a suitable laboratory. In these days of narrow specialization it is pleasant to recall one who had wide interests and yet was always in the forefront of knowledge. He wrote many works and the 'appreciation' concludes with a list of his more important publications.

The Bowles Memorial Travel Scholarship

THE Bowles Memorial Travel Scholarship was established by the Royal Horticultural Society as a memorial to the late E. A. Bowles (1865–1954). The object of the Scholarship is to enable the holder to travel abroad for either or both of the following purposes: (*a*) the collection of plants for introduction to British gardens; (*b*) the study of practical horticulture in other countries. For the years 1964 and 1965 a sum of £500 will be made available for award. Applicants for the Scholarship must be of the male sex, not more than twenty-eight years of age on January 1, 1964, and be a holder of the National Diploma in Horticulture, or a student of, or graduate in, horticulture or botany at a British university, or a past or present student-gardener at the University Botanic Garden, Cambridge, the Royal Botanic Garden, Edinburgh, the Royal Botanic Gardens, Kew, the Royal Horticultural Society's Gardens, Wisley, or other horticultural educational establishment. Applications should be sent, by November 30, to the Secretary of the Royal Horticultural Society, Vincent Square, London, S.W.1, from whom further information can be obtained.

The Night Sky in November

FULL moon occurs on Nov. 1d. 13h. 56m. U.T., new moon on Nov. 16d. 06h. 51m. and full moon on Nov. 30d. 23h. 55m. The following conjunctions with the Moon occur: Nov. 18d. 04h., Venus 3° S.; Nov. 18d. 07h., Mars 3° S.; Nov. 23 05h., Saturn 2° N.; Nov. 27d. 00h., Jupiter 4° N. In addition to these conjunctions with the Moon, Mars is in conjunction with Antares on Nov. 6d. 16h., Mars being 4° N.; Venus with Antares on Nov. 12d. 11h., Venus being 4° N.; and Venus with Mars on Nov. 20d. 22h., Venus being 0·05° S. Mercury, Venus and Mars are too close to the Sun for easy observation. Jupiter sets at 4h. 30m., 3h. 25m. and 2h. 25m. on November 1, 15 and 30, respectively. It is in Pisces, its stellar magnitude is −2·4 and its distance from the Earth on November 15 is 385 million miles. Saturn sets at 23h. 10m., 22h. 15m. and 21h. 25m. at the beginning, middle and end of the month, respectively. It is in Capricornus, its stellar magnitude is +0·9, and its distance from the Earth on November 15 is 920 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Nov. 3d. 20h. 09·5m., 97 Tau (*R*); Nov. 4d. 4h. 11·1m., 106 Tau (*R*). *R* refers to reappearance. The Taurid meteors are active during the first fortnight of the month, but conditions for observation are unfavourable. The Bielid meteors are expected about November 15, the radiant being near R.A. 1h. 32m., Dec. +43°; conditions for observation are favourable. The Leonid meteors are active during November 14–17 with a maximum on November 16–17, the radiant is near R.A. 10h. 8m., Dec. +22°, and conditions for observation are very favourable.

Announcements

DR. J. H. HODGSON, chief of the Seismology Division of the Dominion Observatory, Canada, has been elected president of the International Association of Seismology and Physics of the Earth's Interior. Dr. Hodgson is a director of the Seismology Society of America as well as being a member of various international committees. He was assistant professor of geophysics in the University of Toronto from 1945 until 1949.

THE British Institute of Radiology is holding a meeting on October 17, at which the presidential address "Nothing New?" will be given by Prof. C. B. Allsopp. Further information can be obtained from the General Secretary, British Institute of Radiology, 32 Welbeck Street, London, W.1.

A MEETING to celebrate the centenary of Dr. L. H. Baekeland (1863–1944), the inventor of 'Bakelite', arranged by the Royal Flemish Society of Engineers and the Flemish Chemical Society, will be held in the State University of Ghent during November 22–23. Further information can be obtained from Dr. R. Thiers, Ingenieurshuis, Jan van Rijswijcklaan 58, Antwerpen I.

TWELVE public lectures on "The History of Medicine" will be delivered by Dr. Edwin Clarke in the Wellcome Historical Medical Library, London, on Tuesdays and Thursdays commencing October 15. Further information can be obtained from the Wellcome Historical Medical Library, the Wellcome Building, Euston Road, London, N.W.1.

A MEETING of the Biochemical Society will be held in the Department of Physiology and Biochemistry, the University of Southampton, on October 18. Included in the programme will be a colloquium on "Comparative Biochemistry and Physiology" (chairman, K. A. Munday). Further information can be obtained from H. R. V. Arnstein, National Institute for Medical Research, the Ridgeway, Mill Hill, London, N.W.7.

A SYMPOSIUM on "The Natural History of Aggression", arranged by the Institute of Biology, will be held at the British Museum (Natural History) during October 21–22. Topics under discussion will include: ritualized fighting in animals; aggression in societies of apes; the physiological background to aggression; aggression and mental illness; the origins of war; possible substitutes for war; the nature of aggression as revealed by the atomic age. Further information can be obtained from the Institute of Biology, 41 Queen's Gate, London, S.W.7.

A PRACTICAL four-week residential course in "Administration and Management of Research and Development", arranged by the Comparative Administration Trust, will be held at the Sundridge Park Management Centre, Bromley, during November 10–December 7. The aim of the course is to improve the practical effectiveness of those engaged in administration and management of technical work in industry, in industrial research associations or publicly sponsored research establishments. Topics to be considered will include: the nature of the individual and of the team; the teams in their wider context; special problems of science and technology. Further information and forms of application can be obtained from the Comparative Administration Trust, 30 St. George Street, Hanover Square, London, W.1.

THE ROCKEFELLER FOUNDATION

BESIDES discussing some major innovations in the Foundation's programme in 1962, the President's Review of the Rockefeller Foundation, 1962*, notes some features of the current and operating programmes In medical education substantial grants were made in 1962 to the medical schools of the University of Minas Gerais in Brazil and of the University of Cuyo in Argentina to assist in the establishment of a pre-medical curriculum and strengthen research and teaching The University of Khartoum was assisted in reorganizing its Department of Physiology and the King George's Medical School, University of Lucknow, the development of its Department of Pharmacology, while the Medical Training Centre of the Ministry of Health and Labour of Tanganyika received a grant towards a new training programme for rural physicians Help was also given to the Departments of Preventive Medicine and Pædiatrics, Makerere University College, in developing a field research and training centre in preventive medicine at Kasangati, to the Institute of Child Health of the University of Ibadan, and to the All-India Institute of Medical Science, New Delhi, in developing a teaching and research unit in rural medicine

In the humanities and social sciences a current grant is helping the International Press Institute, Zurich, to promote more effective use of the daily newspaper press in the countries of south and south-east Asia, and the Educational Broadcasting Corporation, New York, was assisted in the initial operation of an educational television channel Among research projects supported in the field of land economics, one at the University of Arizona, Tucson, relates the availability of water to social and economic growth in an arid environment, and programmes in agricultural economics are being supported at the Catholic University of Chili, Santiago In agricultural sciences, on June 30, 1962, 236 students from 28 countries held Foundation scholarships or fellowships for M Sc or Ph D courses at 40 different universities in the United States and Europe Continued support was given to an orientation programme for foreign students entering graduate schools of agriculture in the United States, the Texas Agricultural and Mechanical College System received a grant for studies with a mechanical device for measuring the nutritive value of forage crops during the digestive process in ruminants, and the University of Arizona a grant for investigation of the economic use of scarce water supplies, while establishment of an animal nutrition research centre at Nova Odessa, São Paulo, Brazil, was also assisted

For virus work in 1963 and its operating programme in the general development of professional education the Foundation appropriated some 1 5 million dollars, and the Review outlines the work which led to the discovery of the new virus, oropouche, and the investigation of arboviruses For co-operative projects in agricultural sciences in five countries, the Foundation has appropriated more than 2 6 million dollars in 1963 in addition to 515,000 dollars for the International Rice Research Institute These projects include the Mexican Agricultural Programme, now in its twentieth year, and similar projects in Colombia, at first concentrated on corn, wheat, potatoes and beans, but now yielding results from livestock research of great value in improving beef and dairy cattle, poultry, sheep and swine, Chile (concentrated on wheat and forage legumes and grasses), and India, where hybrid maize varieties adapted to all the major agricultural regions have been developed

During 1962, 723 persons from 58 countries held Foundation fellowships and scholarships, of which 265 were new awards, of the total, 298 were in agricultural sciences and 231 in medical and natural sciences; 3 2 million dollars were appropriated for these activities

CONGENITAL ABNORMALITIES

THE decreasing rate for infant mortality in Great Britain and other parts of the world is bringing greater interest to bear on congenital abnormalities, which, apart from the effects on the children, cause so much distress to their parents The greater part of the August issue of *The Practitioner*[1] is taken up with a symposium on the subject

As C O Carter points out, it was not until 1956 that new cytological techniques confirmed that human beings have a normal complement of 46 chromosomes Non-disjunction may result in gametes being produced possessing 22 or 24 chromosomes Other abnormalities arise through fragmentations, with parts of separate chromosomes coming together in irregular ways, the remaining bits becoming lost About 2 per thousand babies are trisomic for the sex chromosomes, of the patterns XXX, XXY, and XYY Some of these arrangements produce no obvious defect, but all XXY persons suffer from Klinefelter's syndrome, with a eunuchoid body build and azoospermic testes In contrast to these, XO individuals exhibit Turner's syndrome, with dwarfism and abnormalities of the heart and kidneys About 2 per thousand babies are either trisomic for autosomes such as $G21$, $E18$, and $D15$, or they may have a compound of chromosomes $D15$ and $G21$, from which other parts may be lost All these are held to be suffering from Down's syndrome, exhibiting a great variety of derangements, such as deafness, polydactyly and mosaicism As Carter suggests, these findings provide some limited scope for genetic counselling

The most familiar case of abnormality associated with a chromosome derangement is that of the infant mongol This is discussed by A J Keay The affected children have 47 chromosomes, probably through the trisomy of $G21$ The clinical signs are easily recognized, and the intelligence quotients of the affected children range from about 25 to 68 These children are cheerful and responsive to affection, they all should be given some chance of responding to educational care The risk of producing a mongoloid child depends on the age of the mother, amounting to about 1 in 1,000 for young women and rising to around 1 in 50 for those of more than 40 years

The existence of inborn errors of metabolism inherited on a Mendelian basis was first noticed by Folling in 1934 That was a case of phenylketonuria The frequency of incidence is about 1 in 30,000, and the disease is now known to be due to a recessive gene which leads to an inability to metabolize phenylalanine properly, and the affected children show hypertonicity of the muscles and are on the verge of imbecility They respond favourably to a diet low in phenylalanine if it is started sufficiently early This and other inborn errors of metabolism are described by A Goldberg They include alkaptonuria, non-endemic familial cretinism with goitre, some forms of diabetes, galactosæmia, glycogen deposition disease, and many other abnormalities concerned with the metabolism of adrenal steroids, purines, metals, lipids, hæmoglobin and the clotting of blood, porphyrins, bile pigments and renal tubular transport In most cases the abnormalities are the result of enzyme irregularities dependent on recessive genes As Goldberg remarks, it would seem that no metabolic pathway is exempt from the occasional, and sometimes not so occasional, genetically expressed deviation

In their paper on congenital abnormalities of the limbs, J I P James and D W Lamb show that these may take many forms the absence of a hand, arm or fibula, for example, extra digits, syndactyly, 'club foot', etc , along with an extensive list of less-serious defects Some of them appear to be the result of chromosome derangements, others are known to be produced by agents of external origin, while congenital dislocation of the hip is now thought to be brought about by maternal hormones, especially relaxin Clubbed feet and related defects can be improved by gentle manipulation and strapping at an early age, a number of other abnormalities call for surgical treatment, but great care should be taken not to remove stumps of limbs which can be made use of in prosthetic replacement, with which, if in a simple form, the child should be allowed to grow familiar as soon as possible

A D M Jackson deals with congenital abnormalities brought about by agents of external origin, of which the most general are infections Leaving aside infections gaining entry at the act of birth, like gonococcal ophthalmia, and those passed on from mother to fœtus at a late stage in pregnancy, like chickenpox and Coxsackie *B* virus disease, Jackson draws on the investigation initiated by the Ministry of Health and General Register Office, in 1950, and a still larger one in Sweden These investigations show that the most serious abnormalities are due to infections of rubella during the first three months of pregnancy The effects are seen in higher rates than normal for abortions and stillbirths, low birth weight, cataract, heart defects, and deafness The risk that a child will be born with some affliction is about 30 per cent, with deafness as the commonest, deafness appears to be the only serious handicap if the mother becomes infected at later stages in pregnancy To avoid these defects the mother should be immunized against rubella before marriage, even passive immunization within a few days of exposure may be of some help

The British investigation also covered the risk of abnormalities produced by other infections, such as measles, poliomyelitis and influenza, but no clear association between infection and abnormality could be established

Among the congenital defects produced by external agents of an artificial kind, the tragedy of the thalidomide episode has directed attention to those resulting from drug treatment J M Robson deals with these Thalidomide itself is a mild sedative, even in large doses it produces scarcely any toxic effect on man and animals Why it should exert such a drastic influence on the fœtus is a question which still remains obscure There are other drugs, like sodium salicylate and nicotine, in wide clinical use which have not yet been shown to be teratogenic in man although in high doses they have serious effects on the fœtuses of experimental animals A number of other drugs seem to act in much the same way The action on man of 5-hydroxytryptamine still awaits elucidation, it is naturally present in the body, but in large doses it produces many malformations in animals, probably because of its interference with placental function Robson recommends that in introducing new drugs for clinical use great caution should be exercised over those which are teratogenic in experimental animals, particularly if there is a wide discrepancy between the dose which has a harmful effect on the fœtus and that which is toxic to the mother

The remaining paper in the symposium, by J W Millen, is on the effects of radiation He refers to the large amount of work which has been done on experimental animals many congenital abnormalities have been produced, affecting every organ system, and depending on the time, intensity and nature of the radiations, together with the stage in pregnancy Experiences with therapeutic irradiation have shown that similar defects can be produced in man The effect appears to be directly on the fœtus, not mediated by the mother Surveys of the results of the atomic bombs exploded in Japan have reported many cases of microcephaly, which is the only defect that can be linked directly with the intensity of exposure, but other effects may have been masked by fœtal deaths So far there is no convincing evidence that mutations can be produced by irradiation in man, and the risk of harmful mutations being caused by the background radiation of present-day living would seem not to be serious

R WEATHERALL

WORLD DIRECTORY OF VETERINARY SCHOOLS

A *World Directory of Veterinary Schools** has recently been published by the World Health Organization, Geneva, under the auspices of the Food and Agriculture Organization of the United Nations and the World Health Organization There has, in the past, been no available source of information about veterinary schools as a whole, and the *Directory* will be of great use to all those concerned with veterinary science

During the past decade and a half there have been great changes and extensions in veterinary schools The end of the Second World War led to considerable changes in certain European countries, in some instances the changes were merely the result of opportunity after hostilities had ended and there was return to normal life, a matter merely of delay Altered frontiers and other political matters resulted in changes The achievement of self-government in certain former British territories and in those of other European powers has been an important cause of development Whereas there were 6 schools prior to 1947 in India there are now 16 Pakistan has 2

The details for each country are set out according to a standard plan under the same sets of headings, beginning with tables showing the population of the country, the numbers of livestock and details of veterinary activity In the case of each country a table is given of the veterinary schools, date of foundation, numbers of teaching staff, total enrolment and tuition fees Information is given for each country concerning administration, conditions of admission, curriculum and examinations

Scrutiny of the *Directory* shows extraordinary disparity in the numbers of graduates, the numbers of veterinary schools and the numbers of livestock in a country It is of interest to compare essential figures given for livestock populations and the numbers of veterinarians The figures for the United Kingdom concern only the numbers resident in the country, and about 1,800 of the graduates are resident overseas A defect in the quotations of essential figures given in the first table for each country is that there has been some or even considerable delay in reporting them, those given for the United Kingdom refer to 1959 Unfortunately, the wording used in these tables is not very lucid

---

* *World Directory of Veterinary Schools*, 1963 (Published under the auspices of the Food and Agriculture Organization of the United Nations and the World Health Organization) Pp 216 16 Sw francs, 26*s* 8*d* , 5 25 dollars

The following table is made up from data in the book It has been prepared by placing the order of the countries according to the numbers of the larger farm animals horses, cattle, camels and domestic water buffaloes, for the purposes of demonstration of animal wealth the smaller farm animals can be ignored This table shows the enormous farm animal wealth of India, with more than double the numbers of any other country It also brings out the very small numbers in many countries of great prominence

Farm livestock (large animals) (millions)	Veterinary schools	No of veterinarians	
207	16	5,583	India
96	18	20,861	United States
85	8	2,325	Brazil

NATURAL GAS IN THE NETHERLANDS

THE first natural gas field in Holland was discovered and developed by the N V Nederlandse Aardolie Maatschappij (N A M) in 1948 in the province of Drenthe, at Coevorden The gas-bearing formation is at a depth of more than 9,000 ft Coevorden proved to be a small but exploitable field Later, other small gas fields were discovered in the north-eastern provinces of Drenthe and Overijssel, also in the western province of South Holland, but the amount of gas available was relatively small, some 520,000 cubic yards per day, and at that rate a calculated twenty years' supply In terms of energy this quantity of gas per day is equivalent to about 150,000 tons of coal per year, in 1954 the coal production of the Netherlands amounted to 12 million tons, thus the quantity of natural gas available in that year did not represent more than 1 per cent of the total coal production

It was not until August 1959 that the natural gas situation was dramatically changed by the drilling of a well at Slochteren in the province of Groningen which proved the existence of an enormous gas-field, actually the third largest in the world, Panhandle, Texas, being the largest, followed by the Hassi R'Mel gas-field in the Sahara as second After Slochteren No 1 (as it was called), there followed successful strikes of gas at Delfzijl and Slochteren (No 2) in 1960, at Ten Boer in 1961, at Nordbroek in 1962 and at Schildmeer in February 1963 all in the province of Groningen

The total proved natural gas reserves in the Groningen province alone are so far estimated at some 520,000 million cubic yards, the largest in Europe Compared with the French gas-field at Lacq in France, with estimated reserves of 230,000 million cubic yards, the Groningen field is more than double the size A further factor is that the geographical spread of this natural gas deposit may not as yet have been completely determined, possibilities of extensions under the North Sea by off-shore drilling, equally eastwards into West Germany, are by no means unlikely

Production from the Gronginen region will be carried out by N A M , a joint venture of the Esso Petroleum and Shell Companies N A M and the State Mines Department of the Netherlands have formed a partnership "under which they will share the costs and the proceeds of the development of the natural gas on a basis of 60 and 40 per cent respectively" " N A M will deliver all the Groningen natural gas to a new company called N V Nederlandse Gasunie, which was formed on April 6 this year Forty per cent of the new company is owned by the State Mines, 25 per cent each by Esso and Shell and the remaining 10 per cent by the Dutch Government Its function is to purchase, transport and market natural gas in the Netherlands" Further information on these extremely important developments is given in an illustrated article in a recent issue of *Esso Magazine* (12, No 3, 1963) H B Milner

SEARCH FOR PETROLEUM IN AUSTRALIA

IN 1900 there was an accidental discovery of natural gas at Roma, some 300 miles west-north-west of Brisbane, Queensland Since that time there have been many short-lived and unsuccessful attempts to locate oil and gas deposits in commercial quantities in that area But prospecting for oil still continues with persistent enthusiasm and cautious confidence not only in this region but also in other potential places in Australia As recently as 1959 the Commonwealth Government enacted the Petroleum Search Subsidy Act enabling exploration companies to carry out geophysical or bore-hole surveys for new sub-surface stratigraphical information or in prospecting for petroleum The Act provides for subsidy for the cost of operations subject to approval of projects by the Minister of National Development On behalf of the Minister, the Bureau of Mineral Resources, Geology and Geophysics must examine and approve applications made under the Act, maintain surveillance of the operations and, in due course, publish the results Thus has been provided a new stimulus in the time-long search for oil in this continent and four publications recently issued by the Department of National Development (Bureau of Mineral Resources) clearly demonstrate that the provisions of the 1959 Act are working in a most practical manner*

Publication No 8 deals with Frome Rocks No 1 and No 2 Wells, located about 100 miles east-south-east of Broome on the north-west coast of Western Australia, the operations being carried out by West Australian Petroleum Pty , Ltd , No 1 penetrated 734 ft of Recent deposits, thence through normal Jurassic sequence to the Frome Rocks Salt Dome No signs of hydrocarbons were seen No 2 was drilled to more than 7,500 ft , but results were not significant This area does not appear very promising

Publication No 35 takes us back to Roma once again, it deals with the East Roma Seismic Survey, carried out in 1959–60 by Austral Geo Prospectors Pty , Ltd , on behalf of Associated Australian Oilfields N L The conclusion is reached "The complex geology of the East Roma area is such that there are a multitude of positions which are favourable for the accumulation of oil and gas . . The East Roma area should be given first priority for continued drilling and further seismic exploration programmes It seems certain that there is gas in commercial quantities"

Publication No 36 describes the Blue Hills–Logue Seismic Survey, Western Australia, also made in 1959–60 by West Australian Petroleum Pty , Ltd The survey area is some 50 miles south-east of Broome The results clarify the delineation of known anticlinal structures in this area, but petroleum prospects are so far not disclosed

Publication No 39 concerns the Longreach–Silsoe Seismic Survey, Queensland, carried out by Cree Oil of Canada, Ltd , in 1960 This again resulted in fresh structural interpretations in this area, but beyond some oil and gas at certain horizons previously known, there appears to be little encouragement to anticipate commercially valuable petroleum deposits here.

Despite all these results, however, the search for oil and gas still proceeds in Australia, and if the vast gas-fields of the Netherlands and the Sahara (traditionally considered unlikely regions for hydrocarbon accumulations in commercial quantity) are anything to go by, then there is ample reason for prosecuting that search

DETERMINATION OF THE NON-ZONAL HARMONICS OF THE GEOPOTENTIAL FROM SATELLITE DOPPLER DATA

By DR. W. H GUIER

Applied Physics Laboratory, Johns Hopkins University, Silver Spring, Maryland

A LEAST squares determination of values for the coefficients, C_n^m, S_n^m, of the non-zonal harmonics of the geopotential·

$$U(r,\varphi,\lambda) = \frac{K}{r}\left\{1 + \sum_{n=2}^{\infty} \sum_{m=0}^{n} \frac{P_n^m (\sin \varphi)}{r^n} \left[C_n^m \cos m\lambda + S_n^m \sin m\lambda\right]\right\} \quad (1)$$

has been made through $n=m=4$ using Doppler data from the three Satellites 1961 o1, 1961 $\alpha\eta$1, and 1962 $\beta\mu$1 In equation (1)

r = geocentric radius from the Earth's centre of gravity, φ = geocentric latitude, λ = geocentric longitude from Greenwich meridian,

and $P_n^m(z)$ are the associated Legendre polynomials

$$P_n^m(z) = (1-z^2)^{\frac{m}{2}} \frac{d^m}{dz^m} P_n(z) \quad (2)$$

The values of C_2^1 and S_2^1 were constrained to be identically zero in the determination

Table 1 presents a brief summary of the Doppler data which were chosen for the determination The data were chosen as being the best available from the point of view of (1) quality with respect to noise-level, timing errors, presence of ionospheric refraction errors, and stability of the satellites' transmitted frequencies, (2) uniform distribution of station locations over the Earth's surface with particular care taken to avoid an overweight of data from stations located within the continental United States, (3) uniform coverage of the satellite orbit by the data with respect to the angle between the ascending node and the Greenwich meridian

The principal ionospheric refraction contribution was removed by coherently combining two frequencies received simultaneously from the satellite in the Doppler receiving equipment[1,2] To ensure further minimum refraction errors, data were considered only if the maximum elevation of the pass was less than 83° and greater than 20° Finally, data points which corresponded to instantaneous elevations below 13° were deleted, and the remaining data points corrected for tropospheric refraction[3] A typical noise-level for that data finally chosen was roughly 5 parts in 10^{10} of the transmitted frequency Timing errors were judged to be below 0 003 sec (3-sigma value)

The data which survived the foregoing criteria were then grouped by days, one group containing all passes for a given satellite which occurred between two successive midnights (G M T) After grouping, only those were selected which contained ten or more high-quality sets of data from at least five separate stations with at least three being outside the continental United States From Table 1 it can be seen that the fewest groups of data for any one satellite occurred for Satellite 1961 $\alpha\eta$1 This is due to the low inclination of the satellite precluding reception of data from high-latitude stations While considerably more groups of data satisfying the foregoing criteria were available for the other two satellites, the total number of groups chosen for each satellite was limited to being roughly equal to avoid overweighting the data corresponding to a particular inclination In the final choice of groups care was taken to ensure a reasonably even distribution of angles between the ascending node and the Greenwich meridian at the time of the first pass in each group In addition, groups for two different satellites occurring on the same day were avoided to increase the *a priori* probability that the effects of undetected station instrumentation errors and refraction errors were random

Table 1. SUMMARY OF DOPPLER DATA USED

Satellite designation	Inclination (deg)	Semi-major axis (km)	Eccentricity	No. individual satellite passes	No distinct station loc.	No data groups (satellite orbits)	Average No. passes per group	Average time span per group (h)
1961 $\alpha\eta 1$	32 4	7,410	0 010	87	9	8	11	15 9
1962 $\beta\mu 1$	50 1	7,510	0 007	199	15	9	22	22 7
1961 o1	66 8	7 320	0 008	155	13	10	16	23 3
			Totals	441	18	27		

Having made the final choice of groups, a least-squares determination of a satellite orbit for each group was made, resulting in no computed arc of the satellite motion lasting more than 24 h Orbit parameters spanning data over such short time-intervals were chosen because (1) the satellite trajectory could be integrated numerically with negligible error and made unnecessary the very tedious task of solving the perturbed equations of motion to high orders, (2) unknown fluctuations in atmospheric drag and errors in the values for the zonal harmonic coefficients introduce negligible errors

The computer programme used to determine the orbits[4] includes the Sun and Moon forces, although they should introduce negligible errors for these short data spans The resulting differences between the Doppler data points and the corresponding computed values for the Doppler shift (based on fixed initial values for the harmonic coefficients of the geopotential) were used as the final data for the least-squares determination of the differential changes in the values of the non-zonal harmonic coefficients

Very briefly, the least-squares procedure used for determining the non-zonal harmonic coefficients was the following The differences between the theoretical and experimental values for the Doppler shift were assumed to arise wholly from errors in the locations of the tracking stations and values for the non-zonal harmonic coefficients It was further assumed that because of these errors there existed errors in the orbit parameters associated with each group of data Perturbation equations were then derived to express these residuals as a function of differential changes in the three co-ordinates of each tracking station represented in the totality of data, differential changes in each of the six orbit parameters for each group of data, and differential changes in the values of the C_n^m and S_n^m of equation (1) A special IBM 7094 computer programme was designed and coded in which the differential values of the station positions and orbit parameters are continually adjusted to yield an extremum of the mean-square data residuals with respect to these parameters (irrespective of whether the resulting values are reasonable) for any given values for the differential harmonic coefficients Consequently, at any point in the computing process, changes in the values of the differential station and orbit parameters can produce negligible reduction in the mean-square data residuals In this way the station co-ordinates and orbit parameters are effectively eliminated from the least-squares determination of the harmonic coefficients The programme is then iterated until stable values for the differential non-zonal harmonic coefficients are obtained

Table 2 presents the results of the determination using the data summarized in Table 1 Without new data at a different inclination, it is very difficult to estimate the true error in these values, and no attempt has been made to ascribe a realistic error to each coefficient The fact that the station parameters were effectively eliminated from the determination ensures that the principal error in the resulting values for the coefficients arises from correlated errors in the experimental data and not from erroneous values for the station locations Consequently, the efficacy of this method depends principally on there being sufficient experimental data of sufficient accuracy that the build-up of computer error combined with experimental errors does not destroy the sensitivity of the data residuals to the harmonic coefficients once the station and orbit differential parameters are eliminated Several numerical experiments were performed with the amount of data intentionally reduced to the point where a realistic solution would not be expected The objective of the experiments was to obtain criteria for the number of harmonic coefficients which could be evaluated with the data available As expected, these experiments indicated that if stable values for the coefficients were produced with successive iterations, and if their resulting values did not change markedly with changes in the relative weighting of the data residuals, the final values should be trustworthy

Table 2 VALUES OF THE NON-ZONAL HARMONIC COEFFICIENTS

n	m	C_n^n	S_n^m
2	2	$1\ 68 \times 10^{-6}$	$-0\ 64 \times 10^{-6}$
3	1	$1\ 77 \times 10^{-6}$	$0\ 19 \times 10^{-6}$
3	2	$2\ 86 \times 10^{-7}$	$-0\ 25 \times 10^{-7}$
3	3	$1\ 48 \times 10^{-7}$	$1\ 41 \times 10^{-7}$
4	1	$-5\ 69 \times 10^{-7}$	$-4\ 60 \times 10^{-7}$
4	2	$0\ 60 \times 10^{-7}$	$2\ 66 \times 10^{-7}$
4	3	$7\ 90 \times 10^{-8}$	$-0\ 28 \times 10^{-8}$
4	4	$-7\ 85 \times 10^{-9}$	$6\ 56 \times 10^{-9}$

Recognizing that the Tesseral harmonic, $n=2$, $m=1$, should have negligibly small coefficients, a final check on the validity of the values in Table 2 was made by performing a new determination with C_2^1 and S_2^1 added to those coefficients listed in Table 2 The resulting values for those coefficients in Table 2 were not materially altered and the values for the new coefficients were found to be

$$C_2^1 = 1\ 78 \times 10^{-8},$$

$$S_2^1 = -\ 3\ 48 \times 10^{-8} \qquad (3)$$

The fact that they are negligibly small (compared with the values in Table 2 for $m=1$) lends considerable credence to the values given in Table 2

A comparison between the values given in Table 2 and the present literature[5-8] indicates agreement of roughly the same character as the agreement between any two previously published sets of values Consequently, such comparisons add little additional information on the accuracy of the values presented in Table 2

Clearly the overall effort involved in obtaining these results was very large, and it is impossible to acknowledge all the people who made valuable contributions However, I wish to acknowledge especially the contributions of R R Newton and S Yionoulis for their aid in developing the satellite perturbation equations, G Worsley, G C Weiffenbach, P E P White, and their colleagues in connexion with obtaining the experimental Doppler data, and H D Black, C Weisert, R Henderson, and their colleagues for their help in coding and running the complex computer programmes involved

EXACT INTEGRATION OF THE SPACE-CHARGE EQUATION FOR A PLANE DIODE: A SIMPLIFIED THEORY

By DR. D. H. PARSONS

Department of Mathematics, University of Reading

THE relationship between current and potential difference in a planar vacuum diode has been investigated theoretically in two different ways. Child[1] and Langmuir[2] first supposed that all electrons are emitted from the cathode with zero velocity, and that the potential gradient is zero at the cathode. These hypotheses led to the well-known 'three halves power law'. Schottky[3], Epstein[4], Fry[5], Adams (unpublished), Langmuir[6,7] and Blodgett[7] assumed a Maxwellian distribution of velocities of the emitted electrons, and thereby obtained a satisfactory theory. But the latter hypothesis has the drawback that exact integration of the differential equation is impossible, so that a new function has to be calculated numerically.

We shall generalize the simple Child–Langmuir case, making two hypotheses. We suppose (1) that all electrons are emitted from the cathode with the same velocity, this velocity being independent of the anode potential, and small compared with the final velocity attained on reaching the anode, and (2) that the ratio of the (negative) potential gradient at the cathode to the (positive) gradient at the anode is independent of the anode potential.

By using a technique different from that of Child and Langmuir, we shall integrate the differential equation exactly, and obtain a simple relationship between current and potential difference which agrees extremely well with that calculated by Fry[5], and, independently, by Langmuir[6] for a specific example.

Using C.G.S. and electrostatic units, let a be the distance between the electrodes, u the initial velocity of an emitted electron, v its velocity at a distance x from the cathode. Let the potential of the cathode be zero, and let V, V_a be respectively the potential at a distance x from the cathode, and the anode potential. Let m be the mass, and $e(>0)$ be the magnitude of the negative charge of an electron, let I be the current per unit plate area, and $\rho(<0)$ the charge density at a distance x from the cathode. Then we have, from the equations of energy and continuity, and Poisson's equation

$$\left.\begin{aligned} \tfrac{1}{2}mv^2 &= \tfrac{1}{2}mu^2 + eV \\ I &= -\rho v \\ \mathrm{d}^2V/\mathrm{d}x^2 &= -4\pi\rho \end{aligned}\right\} \qquad (1)$$

Let

$$u = 2^{1/2}(e/m)^{1/2}\varepsilon > 0 \qquad (2)$$

Then from (1) and (2) we have

$$v = 2^{1/2}(e/m)^{1/2}\sqrt{(V + \varepsilon^2)} \qquad (3)$$

$$\mathrm{d}^2V/\mathrm{d}x^2 = 4\pi I/v$$

and thus

$$\frac{\mathrm{d}^2V}{\mathrm{d}x^2} - \frac{4\pi I}{2^{1/2}(e/m)^{1/2}\sqrt{(V+\varepsilon^2)}} = 0 \qquad (4)$$

The second-order equation (4) admits two integrating factors, one less obvious than the other. Thus we have

$$-\frac{2\mathrm{d}V}{\mathrm{d}x}\left\{\frac{\mathrm{d}^2V}{\mathrm{d}x^2} - \frac{4\pi I}{2^{1/2}(e/m)^{1/2}\sqrt{(V+\varepsilon^2)}}\right\}$$

$$\equiv \frac{\mathrm{d}}{\mathrm{d}x}\left\{\frac{16\pi I}{2^{1/2}(e/m)^{1/2}}\sqrt{(V+\varepsilon^2)} - \left(\frac{\mathrm{d}V}{\mathrm{d}x}\right)^2\right\} = 0$$

and

$$3\left\{\left(\frac{\mathrm{d}V}{\mathrm{d}x}\right)^2 - \frac{8\pi I}{2^{1/2}(e/m)^{1/2}}\sqrt{(V+\varepsilon^2)}\right\}\left\{\frac{\mathrm{d}^2V}{\mathrm{d}x^2} - \frac{4\pi I}{2^{1/2}(e/m)^{1/2}\sqrt{(V+\varepsilon^2)}}\right\}$$

$$\equiv \frac{\mathrm{d}}{\mathrm{d}x}\left\{\left(\frac{\mathrm{d}V}{\mathrm{d}x}\right)^3 - \frac{24\pi I}{2^{1/2}(e/m)^{1/2}}\frac{\mathrm{d}V}{\mathrm{d}x}\sqrt{(V+\varepsilon^2)} + \frac{48\pi^2I^2x}{(e/m)}\right\} = 0$$

Integrating, we therefore have

$$\frac{16\pi I}{2^{1/2}(e/m)^{1/2}}\sqrt{(V+\varepsilon^2)} - \left(\frac{\mathrm{d}V}{\mathrm{d}x}\right)^2 = A \qquad (5)$$

$$\left(\frac{\mathrm{d}V}{\mathrm{d}x}\right)^3 - \frac{24\pi I}{2^{1/2}(e/m)^{1/2}}\frac{\mathrm{d}V}{\mathrm{d}x}\sqrt{(V+\varepsilon^2)} + \frac{48\pi^2I^2x}{(e/m)} = B \qquad (6)$$

where A and B are independent of x. Since $V = 0$ when $x = 0$, and $V = V_a > 0$ when $x = a$, it follows that if $\mathrm{d}V/\mathrm{d}x < 0$ when $x = 0$ (which we suppose to be the case), there must be a value of x $(0 < x < a)$ for which $\mathrm{d}V/\mathrm{d}x = 0$. At this point, the velocity $v > 0$, that is, $\sqrt{(V+\varepsilon^2)} > 0$, and thus we see, in (5), that $A > 0$, so that the left-hand side of (5) is positive for all values of x $(0 \leqslant x \leqslant a)$.

The boundary conditions are $V = 0$ when $x = 0$, $V = V_a$ when $x = a$. Let the ratio of the potential gradient at the cathode to that at the anode be $-\lambda(1-\lambda)$ $(0 < \lambda < 1)$, so that we may write

$$\left(\frac{\mathrm{d}V}{\mathrm{d}x}\right)_{x=0} = \frac{-4\pi^{1/2}I^{1/2}\lambda p}{2^{1/4}(e/m)^{1/4}}$$

$$\left(\frac{\mathrm{d}V}{\mathrm{d}x}\right)_{x=a} = \frac{4\pi^{1/2}I^{1/2}(1-\lambda)p}{2^{1/4}(e/m)^{1/4}}$$

λ and p being unknown functions of V_a. Putting these values, together with the above boundary conditions, in (5) and (6), we obtain, after a little reduction

$$\left.\begin{aligned} &\sqrt{(V_a+\varepsilon^2)} - (1-\lambda)^2p^2 = \varepsilon - \lambda^2p^2 \\ &2(1-\lambda)^3p^3 - 3(1-\lambda)p\sqrt{(V_a+\varepsilon^2)} + \\ &\qquad \frac{3\pi^{1/2}I^{1/2}a}{2^{1/4}(e/m)^{1/4}} = -2\lambda^3p^3 + 3\lambda p\varepsilon \end{aligned}\right\} \qquad (7)$$

and thence

$$(1-2\lambda)p^2 = \sqrt{(V_a+\varepsilon^2)} - \varepsilon \qquad (8)$$

$$I = \frac{2^{1/2}(e/m)^{1/2}}{9\pi a^2}p^2\{(1-3\lambda)p^2 + 3\varepsilon\}^2 \qquad (9)$$

Since we have shown that the left-hand side of (5) is positive for all values of x, we see from (7) that

$$\lambda^2p^2 < \varepsilon \qquad (10)$$

while, from (8), we also have

$$\lambda < \tfrac{1}{2}$$

Eliminating p^2 between (8) and (9), we obtain, after some reduction

$$I = \frac{2^{1/2}(e/m)^{1/2}V_a{}^{3/2}}{9\pi a^2}\left[\begin{array}{l}\{1 - \lambda^2(3 - 8\lambda)/(1 - 2\lambda)^3\}(1 + \varepsilon^2/V_a)^{1/2} \\ +\{3(1 - \lambda)(1 - 3\lambda)/(1 - 2\lambda)^3\}(\varepsilon/V_a{}^{1/2}) \\ +\{1/(1 - 2\lambda)^3\}(\varepsilon^2/V_a)(1 + \varepsilon^2/V_a)^{1/2} \\ -\{1/(1 - 2\lambda)^3\}(\varepsilon^2/V_a)^{3/2}\end{array}\right] \quad (11)$$

Up to this point we have made no hypothesis concerning the initial velocity, or the potential gradients at cathode and anode We shall now suppose that, except possibly for very small values of V_a, the initial velocity of an electron is independent of anode potential, depending only on cathode conditions, and being small compared with the velocity attained on reaching the anode That is, from (2) and (3) we shall suppose that ε is constant, and that $\varepsilon/V_a{}^{1/2}$ is small

From (10) and (8) we have

$$\begin{aligned}\lambda^2 < \frac{\varepsilon}{p^2} &= \frac{(1 - 2\lambda)\,\varepsilon}{\sqrt{(V_a + \varepsilon^2)} - \varepsilon} \\ &= (1 - 2\lambda)\{\sqrt{(V_a + \varepsilon^2)} + \varepsilon\}(\varepsilon/V_a) \\ &< (\varepsilon/V_a{}^{1/2})\{(1 + \varepsilon^2/V_a)^{1/2} + \varepsilon/V_a{}^{1/2}\}\end{aligned}$$

Thus, if $\varepsilon/V_a{}^{1/2}$ be small, λ^2 is small of the same order Neglecting ε^2/V_a in (11), writing μ for $\lambda^2(3 - 8\lambda)/(1 - 2\lambda)^3$, and ν for $3(1 - \lambda)(1 - 3\lambda)\varepsilon/(1 - 2\lambda)^3$, we obtain

$$I = \frac{2^{1/2}(e/m)^{1/2}}{9\pi a^2}\ \{(1 - \mu)V_a{}^{3/2} + \nu V_a\} \qquad (12)$$

or, expressing I and V_a in amps and volts

$$I = (2\ 33 \times 10^{-6}/a^2)\{(1 - \mu)V_a{}^{3/2} + \sigma V_a\} \qquad (13)$$

where μ and σ are small and positive, μ being dimensionless and σ having the dimensions of the square root of a potential

We now come to our second hypothesis We suppose that the ratio of the potential gradient at the cathode to that at the anode (namely, $-\lambda\ \ (1 - \lambda)$), is constant That is, we suppose λ constant, and therefore that μ, ν, σ here are all constant Equation (13) therefore expresses I in terms of V_a

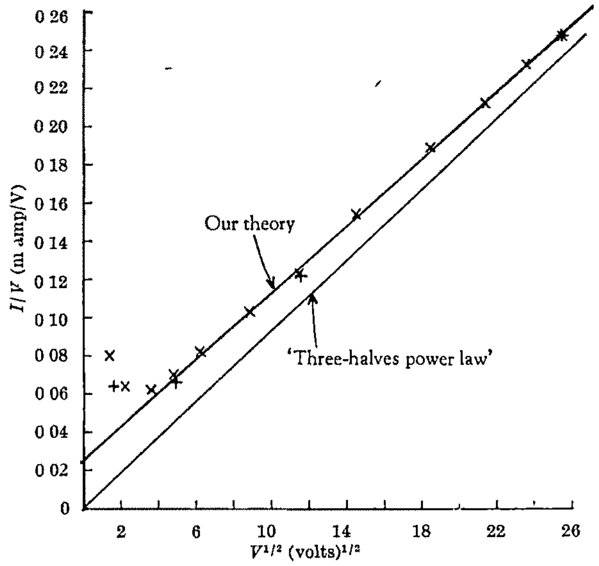

Fig 1 Plot of I/V against $V^{1/2}$ ×, Fry's figures, +, Langmuir's figures $\frac{I}{V_a} = \frac{2\ 33 \times 10^{-6}}{a^2}\{(1 - \mu)V_a{}^{1/2} + \sigma\}$ (μ, σ small positive)

Table 1

I (m amp)	V (V)	I/V (m amp/V)	$\sqrt{V}$ (V)$^{1/2}$
		Fry's figures	
0 16	2	0 080	1 4
0 32	5	0 064	2 2
0 8	13	0 062	3 6
1 6	23	0 070	4 8
3 2	39	0 082	6 2
8	78	0 103	8 8
16	130	0 123	11 4
32	208	0 154	14 4
64	338	0 189	18 4
96	453	0 212	21 3
128	550	0 233	23 5
160	645	0 248	25 4
		Langmuir's figures	
0 16	2 5	0 064	1 6
1 6	24 4	0 066	4 9
16	131 6	0 122	11 5
160	645 0	0 248	25 4

To demonstrate the great accuracy of the results obtained by the simple expression (13), with our hypothesis that μ and σ are small positive constants, we consider an example calculated, on the hypothesis of the Maxwellian velocity distribution, by Fry[5] and by Langmuir[6] This is the case of a cathode of tungsten at 2,400° K, the plate separation being 0 5 cm Noticing that (13) may be written in the form

$$I/V_a = (2\ 33 \times 10^{-6}/a^2)\{(1 - \mu)V_a{}^{1/2} + \sigma\}$$

we plot I/V_a against $V_a{}^{1/2}$ The excellent straight line obtained confirms our hypothesis that μ and σ are constants The slight deviation from the straight line for the smallest values of V_a is due to the error in neglecting ε^2/V_a at this end of the range, in deriving (12) from (11)

The intercept on the axis of (I/V_a) and the slope of the line give, for this example, the values $\mu = 0\ 05$, $\sigma = 2\ 7$ (volts)$^{1/2}$

FREE-ENERGY DIFFERENCE BETWEEN THE ALPHA AND BETA STATES IN KERATIN

By M FEUGHELMAN

C S I R O Division of Textile Physics, Wool Research Laboratories, Ryde, Sydney

WHEN a keratin fibre is extended, the high-angle X-ray diffraction pattern shows a disappearance of α-keratin, as indicated by the 5 1 Å meridional repeat Bendit[1] has shown, and Skertchly and Woods[2] have confirmed, that this disappearance of α-keratin and the appearance of the β-keratin pattern are continuous over the extension range of 0–70 per cent for wool fibres in water This indicates that the opening up of the α-crystallites and the formation of the β-crystallites occur continuously, and Bendit[3] has suggested that, at any fixed extension, equilibrium is established between α-crystallites ⇌ liquid phase ⇌ β-crystallites Estimates from mechanical

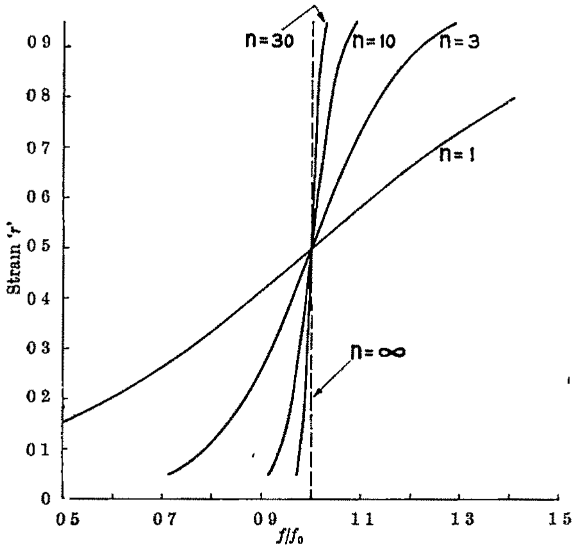

Fig. 1. Plot of the equilibrium strain 'r' in equation 1 (see text) against the stress ratio f/f_0 for different values of 'n', the number of molecular units acting co-operatively in the unfolding and folding of α- and β-crystallite units

measurements on single fibres of the free-energy difference between the units in the α- and β-crystallites have been made by a number of authors[5,6,11]. However, because their measurements are not continued until mechanical equilibrium was obtained, their values were high. Values of the free-energy difference are estimated in this article from mechanical data obtained at mechanical equilibrium.

Let the free-energy difference between the individual units in the α- and β-crystallites be ΔF^* calories/mole. The 'liquid' phase intermediary between the α- and β-states will be assumed to be at a free-energy level above that of the α- and β-states. In these circumstances at stress equilibrium the strain 'r', expressed as a fraction of the maximum strain (when all the structure is in the 'β'-state), may be shown, from the work of Burte and Halsey[4], *et al.*[5,6], to be

$$r = \frac{1}{e^{n\left(\frac{\Delta F^*}{RT} - 2af\right)} + 1} \qquad (1)$$

where f is the force acting on the individual molecular chain, n is the number of molecular units acting co-operatively, in the sense that they must fold or unfold simultaneously, R is the universal gas constant, T is the absolute temperature in degrees, and a is a quantity dependent on the temperature and the volume swept out by the unfolding structure (see equation (2)).

For a large value of n (as might be expected in a crystalline structure), the value of r varies rapidly from zero to unity for values of f close to $f_0 = \Delta F^*/2aRT$. For all values of 'n', $f = f_0$ at $r = 0{\cdot}5$. In Fig. 1 the relationship between the strain 'r' and the force 'f' expressed as a fraction of f_0 demonstrates how with increase of the value of 'n' rapid changes of 'r' occur for values of 'f' close to 'f_0'. Hence for most values of strain at which both α- and β-crystalline phases are present the value of f is almost constant. The approach here has been on the basis of the rate process theory. The same value of 'f' may be obtained by application of the analogue of the Clausius-Clapeyron equation to the equilibrium between two crystalline phases[7].

However, the latter approach only applies for $n = \infty$ and does not indicate, for smaller values of 'n', the deviation from constancy of the force 'f' as the ratio of the two crystalline fractions varies. The stress-strain curve for a wool fibre in water at room temperature has a region between about 2 and 30 per cent strain (in Fig. 2, AB the yield region) in which little change in the stress-level occurs over a large strain range. Several authors[5,6] have analysed this region of the stress-strain curve in terms of an $\alpha \rightleftharpoons \beta$ transformation. With extension into the post-yield region (BC), where there is a rapid increase in stress with extension, there is no discontinuity in the graph of X-ray intensity at 5·1 Å against extension for fibres extended in water. However, the normal stress-strain curve, carried out over periods of minutes, is not an equilibrium curve. Stress measurements on Corriedale wool fibres held extended in water at 45° C at 15 and 45 per cent strain indicated that stress equilibrium was reached after about 1,300 min (Fig. 3). The mean value of the stress (based on the wet diameter) for fibres extended 15 and 45 per cent was $1{\cdot}7_3 \times 10^8$ dynes/cm^2, and $1{\cdot}5_0 \times 10^8$ dynes/cm^2 respectively. As pointed out by Ciferri[7], a similar value for the equilibrium stress was obtained in Wood's[8] stress relaxation measurements. This suggests that the value of the critical stress f_0 to maintain equilibrium in a structure including both the α- and β-forms is approximately $1{\cdot}5 \times 10^8$ dynes/cm^2. A further estimate of the equilibrium stress was obtained in which the stress was approached from a lower value. Fibres were swollen and contracted in 8M lithium bromide solution at room temperature to the first stage of contrac-

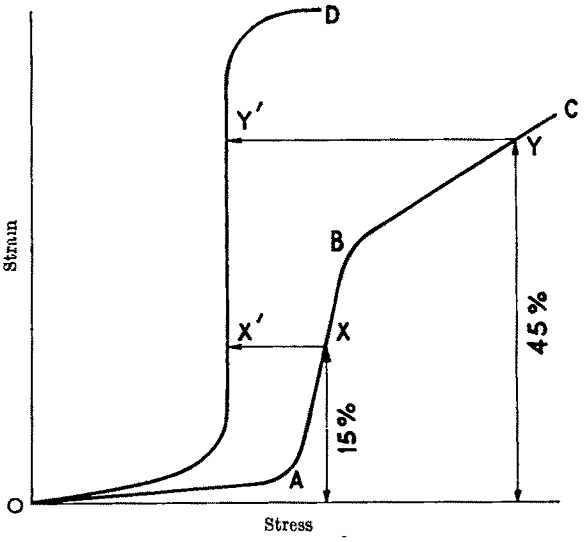

Fig. 2. A typical stress-strain curve of a wool fibre in water ($OABC$) showing the three distinct regions, the Hookean (OA), yield (AB) and post-yield regions (BC). Also shown is the equilibrium stress-strain curve OD

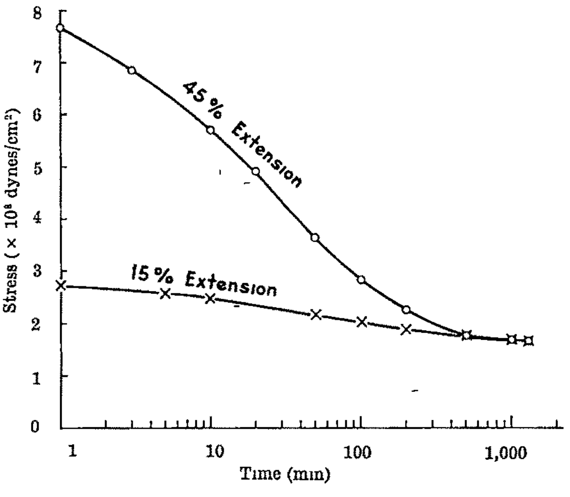

Fig. 3. The stress relaxation of two typical Corriedale wool fibres, one at 15 per cent extension, the other at 45 per cent in water at 45° C. The fibres initially are at different stress-levels (as indicated by points X and Y in Fig. 2) and come to equilibrium after about 1,300 min to the same stress-level (points X' and Y' in Fig. 2)

tion and then extended to 15 per cent above their original native length The lithium bromide was then washed out with distilled water, a treatment which has been shown to restore the fibre to its native state[9] The stress in the extended fibres rose from a lower value in the lithium bromide solution to an average value of 1 $3_1 \times 10^8$ dynes/cm^2 in the water X-ray diffraction patterns of these fibres in their extended state showed that the structure had returned to that of a normal fibre in water The process of washing out a swollen, extended fibre would not be expected to introduce any temporary stress, such as XX' and YY' in Fig 2, the introduction of such stress would mean formation under tension of bonds and entanglements[10] which are unstable when under tension It follows that the stress of 1 $3_1 \times 10^8$ dynes/cm^2 represents the stress necessary to maintain the α- and β-crystalline phases in equilibrium, and as such is in reasonable agreement with the previous figure of 1 5×10^6 dynes/cm^2

If the energy barrier between the α- and β-crystalline phases is assumed to be symmetrical, then the value of a in equation 1 is given by[4]

$$a = \frac{V}{2kT} \tag{2}$$

where V = volume of the molecular flow unit, and k = Boltzmann's constant, therefore

$$\Delta F^* = 2f_0 RT$$
$$= f_0 V \frac{R}{k} = f_0 VN \tag{3}$$

where N = Avogadro's number

The α—β translation distance is 1 8_4Å(3 33Å – 1 45Å) in the fibre direction Assuming hexagonal packing of the α-helices, resulting in the X-ray diffraction pattern having the 9 8 Å equatorial reflexion, the value of V is 200 Å^3 If the force f_0 is due only to the crystalline part of the keratin structure, then, with f_0 = 1 5×10^8 dynes/cm^2 based on a wet fibre diameter, a flow volume of 200 Å^3, a diametral swelling dry to wet (in water) of 16 per cent, and for an assumed crystalline fraction-range of 0 2–0 5, it follows that the value of ΔF^* ranges from about 3 to about 1 kcal/mole Previous values[5,6,11] obtained for the difference in free energy between the folded and unfolded states of the polypeptide chains in keratin range from 4 5 to 10·5 kcal/mole These higher values are due to the fact that equilibrium measurements of f_0 were not obtained In these circumstances the values of f_0 included a large component of force which disappears with time (Fig 3)

It should be further noted that, with the reduction of disulphide content of wool fibres[10] the value of f_0 is reduced Whether removal of disulphide reduces the free-energy difference between the α- and β-states or reduces the effective crystalline fraction of the fibre is not clear

SOIL MOVEMENT ON SLOPES

By Dr. ANTHONY YOUNG
University of Sussex, Falmer, Brighton

IN a previous communication[1] I described techniques developed to measure the rate of movement of soil on slopes, and reported preliminary results Measurements of movement over a 4-year period have now been obtained

The technique is illustrated in Fig 1 On each of 5 sites a trench was dug through the soil and 6 reference pegs were firmly embedded in the rock beneath, 3 near the up-slope and 3 near the down-slope end of the trench The distances from each rod to the reference pegs were measured twice, thus for each rod the distances AB and AC were the means of 6 measurements The positions of the rods were obtained by solving the triangle ABC The plots were established in October 1958, and the trenches filled in, in October 1962 they were re-excavated and the measurements repeated The movements of the rods were derived from changes in the mean lengths of AB and AC

The plots were sited on the east side of Alport Dale, North Derbyshire (Nat Grid Ref *SK*/133921), on slopes of 25°–30°, at 350 m altitude The soil is a yellowish-brown sandy loam, passing into Millstone Grit sandstones (Upper Carboniferous) at approximately 50 cm Above the roots and 5-cm humus There is a dense grass cover, with mineral soil are horizons of 5-cm undecomposed grass *Deschampsia flexuosa* dominant The mean monthly temperature is 1 8° C in January and 13 7° C in July, and the mean annual rainfall is 1,400 mm

After rejecting rods which showed inconsistent movements, assumed to be caused by disturbance during re-excavation, results from 57 rods were obtained These results are shown in Table 1 and Fig 1 The mean movement in the humus horizon was 3 3 mm, while in the horizon of undecomposed organic matter irregular movements of up to several centimetres occurred In the mineral soil most movements were of approximately 2 mm, and were in directions intermediate between vertical and perpendicular to the ground surface There was no systematic variation in the amount of movement from 50 to 350 cm depth, in the upper 50 cm movements were slightly more than 2 mm, whilst below 350 cm they were of the order of 1 mm

The unexpected feature of the results is that the components of movement perpendicular to the ground surface substantially exceed the parallel (down-slope) components. This is difficult to explain in terms of soil creep, in which material is removed from a slope by transportation to the slope foot The perpendicular movement could be accounted for by a loss from the soil of material released by weathering and carried away in solution or suspension by ground-water, thereby causing a direct removal of material from the slope The results suggest that this

Table 1 MOVEMENT OF RODS BURIED IN THE SOIL ON 25°–30° SLOPES DURING FOUR YEARS

Depth below surface of mineral soil (mm)	No of rods	Mean movement		Components of movement parallel to, and perpendicular to, ground surface	
		Distance (mm)	Angle, relative to perpendicular to ground surface (θ in Fig 1)	Parallel (mm)	Perpendicular (mm)
Humus horizon	11	3 3	23°	1 3	3 0
0–50	9	2 3	25°	1 0	2 1
51–100	7	1 9	18°	0 6	1 8
101–150	6	2 1	12°	0 4	2 0
151–200	4	1 8	4°	0 1	1 8
201–250	7	1 8	11°	0 3	1 8
251–300	4	1 9	20°	0 6	1 8
301–350	4	2 0	0°	0 0	2 0
351–550	5	1 2	5°	0 1	1 2

process is more important in slope retreat than is the down-slope movement of soil creep

The unit for measuring volumetric down-slope movement of soil is the volume of soil moved annually across a plane perpendicular to the ground surface and parallel with the contour of the slope. for unit horizontal distance along the plane, expressed in cm³/cm/yr From Table 1 a down-slope movement of 0 46 cm³/cm/yr is obtained, this compares with 0 6 cm³/cm/yr previously obtained from observations over 2 years[1] If a soil depth of 50 cm is assumed, this may be extrapolated to give a mean down-slope movement of the soil layer of the order of 1 cm in 100 years

The amount of slope retreat corresponds to the movement of the mineral soil perpendicular to the ground surface Taking a mean value of 2 0 mm over four years, this may be extrapolated to give a slope retreat of 5 cm in 100 years Sources of error in measurement are such that the precise values obtained are not significant, but if the order of movement is correct, it may be concluded that under present climatic conditions, on soil-covered slopes of 20°–30°, slope retreat occurs at a rate of the order of 500m per million years This relatively high value is in accord with the recent trend towards attributing the evolution of land-forms to shorter periods of time than was previously believed[2] Under colder climatic conditions in Sweden, and for rock cliffs, Rapp[3] has measured the present rate of slope retreat at 0 04–0 15 mm/yr, equivalent to 40–150m per million years

I acknowledge with thanks permission to site these experiments on Forestry Commission land The work was assisted by a grant from the Research Fund of the University of Sheffield

CONFORMATION OF OCTACHLORONAPHTHALENE

By Dr G GAFNER and Dr F H HERBSTEIN

National Physical Research Laboratory, Council for Scientific and Industrial Research, Pretoria

OCTACHLORONAPHTHALENE is severely overcrowded, as the distance between α-substituents in the hypothetical regular and planar molecule would be 2 4 Å, whereas the closest approach found between chlorine atoms in different molecules in crystals is about 3 5 Å Furthermore, the overcrowding of the α-chlorines cannot be effectively reduced by in-plane splaying apart because of buttressing by the β-chlorines Larger deviations from planarity are thus expected than have been found for 1 4 5 8-tetrachloronaphthalene[1,2]

We have recently analysed the crystal structure of octachloronaphthalene, and the available results give the molecular conformation unequivocally The structure was determined by Patterson methods and a three-dimensional least-squares refinement was carried out on an IBM 704 computer using the *ORXLS* programme of Busing and Levy The R factor is 21 per cent at the present stage of refinement of the 2160 visually-measured intensities Separate scale factors for $h0l$ to $h6l$ layers have been used and separate isotropic temperature factors for all atoms The crystallographic data[3] are

$$a = 19\ 48 \pm 0\ 03,\ b = 7\ 30 \pm 0\ 04\quad c = 9\ 76 \pm 0\ 01\ \text{Å}$$

$$\beta = 111°33' \pm 5'\quad \text{Space group } P2_1/a\quad Z = 4$$

$$\rho_{meas} = 2\ 08,\ \rho_{calc} = 2\ 07\ \text{gm/cc}\quad \text{Needle axis } [010]$$

The atomic parameters and their estimated standard deviations are given for one molecule (the asymmetric unit) in Table 1 The results derived from these values are shown in Fig 1

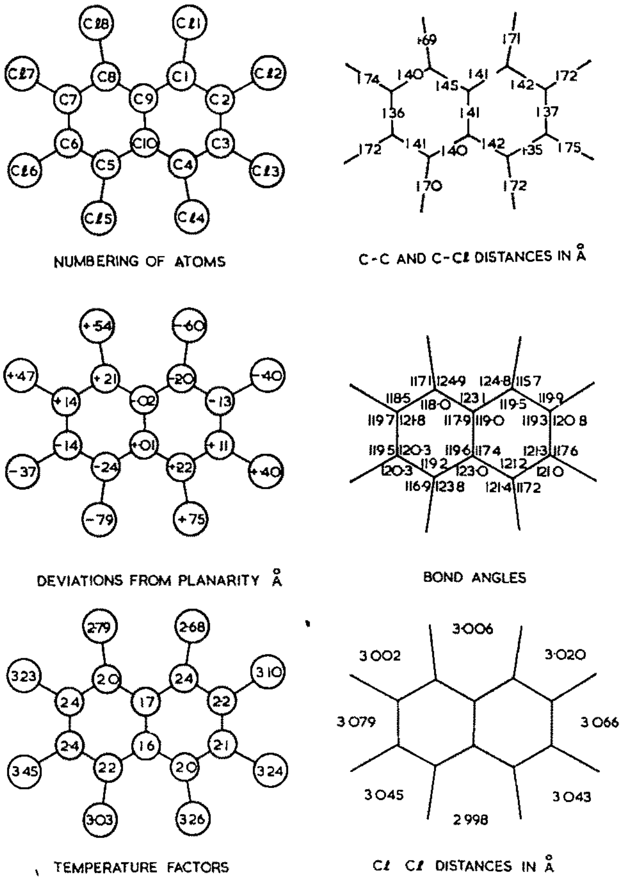

Fig 1 Numbering of atoms, molecular dimensions and isotropic temperature factors The estimated standard deviations are σ(Cl ··· Cl) = 0.007, σ(C–Cl) = 0.018, σ(C–C) = 0.024 Å, σ(CĈCl) = 1.3°, σ(CĈC) = 1.5°

The mean C–C distance is 1.40 Å and the mean C–Cl distance is 1.72 Å, both these averages are as expected and none of the differences between the individual distances and the appropriate mean, nor between the bond angles within the carbon rings and 120°, is statistically significant The deviations of the atoms from the mean molecular plane (calculated by the method of Schomaker *et al* [4], giving Cl and C atoms relative weights of 10 and 1 respectively) are highly significant and establish the conformation of the molecule The overcrowding of α-substituents is relieved by out-of-plane displacements, in different directions within a pair, of between 0.54 and 0.79 Å and an increase of the angles of type Cl 1Ĉ1C9 to a mean of 123.7° The β-substituents are displaced by between 0.37 and 0.47 Å from the mean molecular plane The most interesting feature of the molecular conformation is that adjacent α- and β-chlorine atoms (for example, Cl 1 and 2) are displaced in the same direction The carbon atoms follow the chlorines to which they are bonded with displacements about one-third as large as those of the chlorines

The free molecule of octachloronaphthalene would be expected to have D_2-222 symmetry Fig 1 shows that highly significant deviations from this symmetry occur for the molecule in the solid state The main deviations from D_2 symmetry are

(1) The smaller out-of-plane displacements and temperature factors of Cl 1 and Cl 8 compared with those of Cl 4 and Cl 5

(2) The shorter Cl 1 ··· Cl 2 and Cl 7 ··· Cl 8 distances compared with Cl 3 ··· Cl 4 and Cl 5 ··· Cl 6

These deviations are a consequence of packing forces and can be qualitatively explained in terms of the molecular arrangement shown in Fig 2 The crystal is composed of stacks of molecules with stack axes parallel to [010] The molecules within any one stack are related by a screw axis parallel to [010] and are successively displaced by about 2.4 Å in positive and negative directions parallel to [$\bar{2}$01] This results in one half of each molecule being positioned between the molecules above and below it, the other half being essentially free The packing forces thus cause Cl 1 and Cl 8 to have smaller out-of-plane displacements than Cl 4 and Cl 5 The lower temperature factors of Cl 1 and Cl 8, compared with those of Cl 4 and Cl 5, and the shorter Cl 1 ··· Cl 2 and Cl 7 ··· Cl 8 distances as compared with Cl 3 ··· Cl 4 and Cl 5 ··· Cl 6 are also consistent with the operation of compressive packing forces on Cl 1 and Cl 8 However, it should be noted that some of these latter differences are not yet securely established statistically

The closely analogous molecule octamethylnaphthalene has been investigated by Donaldson and Robertson[5] and found to possess exact D_2-222 symmetry in the solid state by virtue of its position in the unit cell It can thus have either of the following conformations

(I) As found for octachloronaphthalene in the present work, that is, with the adjacent substituents within each α- or β-pair displaced in different senses from the mean plane and with adjacent α–β substituents displaced in the same direction

(II) With adjacent substituents displaced in opposite senses independent of whether they constitute an α- or β-pair or not

Donaldson and Robertson pointed out that the two-dimensional data obtained by them did not permit a direct choice to be made between these two conformations, as II was considered to be the more plausible, their subsequent discussion was based on the assumption that this was in fact the true molecular conformation In the light of the present results there seems little doubt that conformation I, and not II, is adopted by octamethylnaphthalene

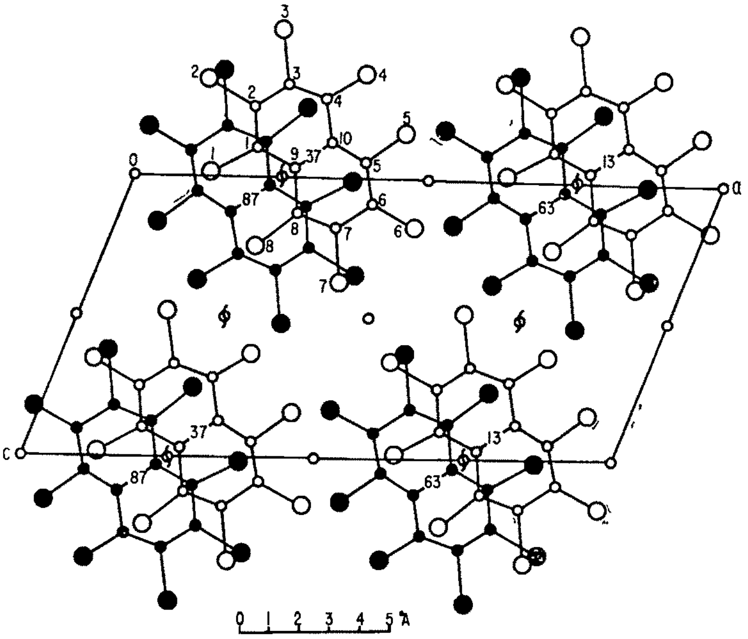

Fig 2 Packing of molecules in the crystal, seen in projection on (010) The numbered atoms are those the parameters of which are listed in Table 1 The v co-ordinate of the mean molecular plane is denoted at the centre of C9–C10 for each molecule, the upper (puckered) layer of molecules has full circles, the lower open circles The intermolecular distances are those expected for normal van der Waals contacts between different molecules

An explanation for the preference for conformation I over conformation II can be given in terms of the molecular strain energy which can be considered to consist of two parts (*a*) the energy associated with close approaches between adjacent substituents, (*b*) the skeletal strain energy

Conformation I minimizes the skeletal strain energy at the expense of increased substituent interaction energy In contrast, conformation II does the opposite as in this conformation the carbon atoms would form chair-shaped rings by following the chlorine deviations from planarity Chair-shaped rings would only be expected to be energetically preferred when bonding is tetrahedral, for example, in *cyclo*hexane A diminution in skeletal strain energy would thus be expected on going from the hypothetical double chair-shaped naphthalene nucleus to the twisted (propeller-shaped) naphthalene system found in the present work This diminution must be numerically greater than the increase in repulsive energy associated with type Cl 1 Cl 2 chlorine pairs, on going from conformation II to I

Another naphthalene derivative which is probably deformed in the same way as octachloronaphthalene is tetrabenzonaphthalene, for here coupling of adjacent α- and β-carbon atoms of the naphthalene nucleus by the substituent rings precludes the adoption of conformation II A partial analysis of the crystal structure of tetrabenzonaphthalene has been reported[6], but the only definite conclusion that could be drawn from the one projection obtained was that the molecule was not centrosymmetric The naphthalene ring system in 1 4 5 8-tetrachloronaphthalene also shows a tendency towards the twisted conformation, but the deviations from planarity (less than 0 05 Å) are much smaller than in octachloronaphthalene

The novel features established by this analysis are the propeller-like conformation of octachloronaphthalene and the appreciable influence of the crystal packing-forces on its symmetry in the solid state Detailed information about the naphthalene ring system and the thermal vibrations of the molecules in the crystal will require more accurate intensities, and it is hoped to re-measure these by counter techniques

SOLVENT RETENTION AND GEL FORMATION IN POLYVINYL CHLORIDE

By M. A. CROOK*

British Insulated Callender's Cables, Ltd , Research Organization, London

IT is generally recognized that cross-linking with gel formation, or degradation with decrease in molecular weight, can occur in polyvinyl chloride depending on the irradiation conditions[1–3] and on the presence of additives in the polymer[4,5] It has also been shown that gel formation in polyvinyl chloride follows closely the form required for a chain reaction[6] and that considerable differences in gel formation may be observed between powdered polyvinyl chloride and that cast in the form of a film

It is proposed to give an account of the work which has been done in this laboratory using the normal technique of casting films from a solvent, and to discuss the effect of the residual solvent on the cross-linking process The preliminary results apparently indicated that the percentage gel obtained on irradiation is proportional to the thickness of the film, however, infra-red examination of polyvinyl chloride cast from tetrahydrofuran (THF) shows in fact that in spite of prolonged pumping under high vacuum to apparently constant weight, such films may contain a considerable amount of solvent in them Films cast from chlorobenzene and methyl ethyl ketone show similar behaviour , a film pumped under high vacuum to apparently constant weight may contain 2–4 per cent solvent The variation of gel fraction with percentage solvent depends on the radiation dose given, Fig 1 shows this variation for two films of thickness 0 20 and 0 05 mm cast from chlorobenzene, the percentage solvent was determined by infra-red absorption measurements

Unfortunately, in spite of prolonged pumping of the film (> 100 h) at a pressure of less than 1μ and at a temperature of 60° C, it has not been possible to obtain samples of the required shape and thickness with less than 0 25 per cent solvent without incurring some degradation Attempts to remove solvent by solvent exchange with either methyl alcohol or carbon disulphide were also unsuccessful Films of thickness 0 05–0 1 mm thick cast from chlorobenzene, immersed in carbon disulphide for 28 days, still contained 0 3–0 4 per cent chlorobenzene Similar films cast from tetrahydrofuran also contained residual solvent[7]

Examination of the solvent-containing films before and after irradiation shows no substitution of the solvent molecules by chlorine nor hydrogen atoms, and extraction of the sol fraction almost completely exchanges the solvent present in the film with that used for extraction This shows that the solvent molecules are not chemically attacked nor are they attached to the cross-linked material This is contrary to the experience of Alexander and Toms[8], who showed that naphthalene was incorporated in films of polymethyl methacrylate on irradiation These polyvinyl chloride films also obey the relationship log $S = \gamma(R - R_0) + 2$, where S is the percentage sol fraction at dose R megarads and R_0 the gel dose, both γ and R_0

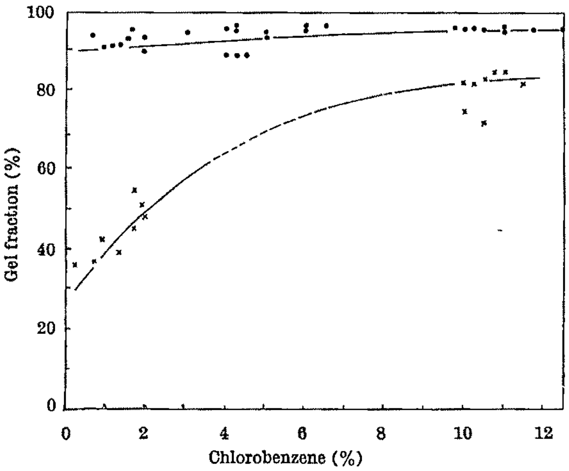

Fig 1 Variation of gel fraction with percentage chlorobenzene in a sample of polyvinyl chloride ('Corvic 65/8' supplied by Imperial Chemical Industries, Ltd) ●, 54 Mrads, ×, 27 Mrads

* Present address Department of Chemistry, Borough Polytechnic, London, S E 1

Table 1 VARIATION OF PERCENTAGE OF CHLOROBENZENE IN POLYVINYL CHLORIDE ON IRRADIATION*

Dose (Mrad)	% Chlorobenzene before irradiation	% Chlorobenzene after irradiation	% Chlorobenzene after extraction†	% Gel determined by extraction with THF
27	10 4	10 0	0	82 7 ± 1 5
54	10 9	10 1	0	95 1 ± 0 3
108	10 6	8 5	0	96 9 ± 0 3

VARIATION OF PERCENTAGE OF METHYL ETHYL KETONE (MEK) IN POLYVINYL CHLORIDE ON IRRADIATION‡

Dose (Mrad)	% MEK before irrad	% MEK after irrad	% MEK after extraction	% Chlorobenzene from extraction	% Gel determined by extraction with chlorobenzene
54	3 0	2 7	0 2§	8	71 6 ± 2 2
108	3 0	2 0	0 5	11	95 4 ± 1 4
216	1 5	1 0	00	16	102 ± 1 3

All the samples were irradiated at 60° C and under high vacuum, the cell was opened to air 2 min after irradiation and immediately extracted with solvent These results are the average of at least four separate samples.

* The results fit the equation log $S = 2 - 1\ 22 \times 10^{-2}\ (R - 34\ 5)$, with a standard deviation of ± 0 18

† The infra-red absorption of THF in the extracted samples was always too large to measure

‡ The results fit the equation log $S = 2 - 1\ 46 \times 10^{-2}\ (R - 16\ 5)$ when the solvent content is 3 per cent

§ After irradiation considerable broadening of the peak of the MEK absorption spectra was observed due to interference of oxidation products formed during the extraction process, hence the values quoted for percentage MEK after extraction are upper limits only Antioxidant added to prevent this oxidation was preferentially absorbed by the polyvinyl chloride and gave even greater interference of the spectra

depend on the amount of solvent and its nature The results are given in Table 1

Hence any free radical chain mechanism proposed for irradiation processes in polyvinyl chloride must allow for the presence of small quantities of solvent molecules which markedly affect the radiation properties without themselves of necessity being involved chemically Such a possible mechanism may be described as follows If the primary process of irradiation results in the production of free radicals[9] either directly or through intermediate ions[10], then such radicals are probably formed in an excited state with a considerable quantity of excess energy which presumably is present as vibration energy In any polymer this vibrational energy is available to overcome steric factors for cross-linking between adjacent molecules In the case of polyvinyl chloride, however, some of this energy may be removed by the process of 'splitting off' a hydrogen chloride molecule, such a process would be favourable as the free radical would then become resonance stabilized, but would have less energy available for cross-linking This accounts for the exceptional stability of some polyvinyl chloride radicals[11], and for the loss of hydrogen chloride which occurs after irradiation and on heating[12]

Now it is known that when polyvinyl chloride is irradiated in solution, even in very dilute solution, it cross-links with a high degree of efficiency[2], and this is explained as being due to the mobility of the polymer molecules Therefore, if the local presence of a solvent molecule enables part of a polyvinyl chloride chain to acquire more freedom of movement, this solvent molecule will have increased the cross-linking efficiency without itself having taken part in the reaction This idea is further supported by the work of Shinohara *et al* [12], who showed that treatment of polyvinyl chloride with tetrahydrofuran after irradiation but under vacuum increases the amount of cross-linking

I thank Dr R M Black for his encouragement and advice, Mrs D E Speed and Mrs R Ross for carrying out the infra-red measurements and Dr L G Brazier, director of research, British Insulated Callender's Cables, Ltd , for permission to publish this communication

ABNORMAL GLUCOSE TOLERANCE IN REPEATEDLY BRED RATS WITH ARTERIOSCLEROSIS

By PROF BERNARD C. WEXLER and DR CHARLES T. FISCHER

May Institute for Medical Research, Jewish Hospital of Cincinnati, and Department of Pathology, University of Cincinnati College of Medicine, Ohio

PREVIOUS work in this laboratory has demonstrated that male and female rats which have been repeatedly bred will develop arteriosclerosis[1-4] The early arterial lesions consist of subintimal deposition of mucopolysaccharides which are capped by fibrous tissue More advanced lesions consist of marked alterations in medial mucopolysaccharides, elastosis and dystrophic calcification In addition to the arteriosclerosis, these animals also develop a fatty liver, hyperplasia of the islets of Langerhans with beta cell degranulation and hypertension All these degenerative changes become more pronounced with each successive breeding These changes are also accompanied by progressive adrenal hyperplasia and thymic involution The gravimetric and histologic changes in the adrenal and thymus glands coupled with *in vitro* investigations of the adrenal steroid production of these animals indicated that a state of hyperadrenocorticism existed There was reason for believing that the fatty liver and the islet hyperplasia could be related to either the hyperadrenocorticism or to the existence of a diabetes-like condition Further, the mucopolysaccharide nature of the arteriosclerotic lesions in these breeder rats, the high incidence of arteriosclerotic complications in diabetic patients and the concomitant existence of diabetes, arteriosclerosis and hyperadrenocorticism in Cushing's syndrome served as a general background to provide some basis for interrelating the variety of degenerative changes observed in breeder rats Therefore, it was decided to investigate the carbohydrate tolerance of these animals Glucose tolerance tests were performed on arteriosclerotic breeder rats and non-arteriosclerotic virgin rats to determine whether the conditions of hyperadrenocorticism, fatty liver, islet hyperplasia and arteriosclerosis observed in breeder rats were also accompanied by any abnormal carbohydrate metabolism

One-hundred-and-forty virgin Sprague–Dawley rats, free of any arteriosclerosis (80 females and 60 males), served as controls These virgin rats were 10–12 months old and were approximately the same age as the breeder rats The virgin control animals were divided into equal groups so that blood-sugar determinations could be made at the following intervals 0 h (fasting-level), 0 5, 1, 2, 3, and 5 h A total of 215 female and 70 male Sprague–Dawley breeder rats were used. The male breeders were arranged so that there were 15, 15, 10, 10, 10, and 10 animals in the six groups investigated As in the controls, the male breeders were killed at 0–5 h intervals The male breeders were arbitrarily divided in this fashion because

their arterial lesions cannot be determined grossly, thus obviating any attempt to correlate abnormal carbohydrate metabolism with gross arterial abnormality On the other hand, female breeders do develop arteriosclerosis which can be easily detected by gross examination Therefore, the female breeders could be categorized according to the degree of gross arterial pathology exhibited at autopsy Female breeders with no grossly visible arteriosclerosis were classified as 'clear', those with thin annular streaks in the abdominal aorta as 'minimal', those with discrete plaques in the arch of the aorta in addition to having lesions in the abdominal aorta as 'moderate', and those with plaques in all portions of the aorta as 'severe' These animals were killed after the test dose of glucose at the same time-intervals as the controls and male breeders A record was kept of the degree of gross arteriosclerosis in female breeders found at autopsy and this was later correlated with the blood sugar values

Prior to the time of the glucose tolerance test, all the animals had been stabilized on a regular 'Rockland Rat Chow' diet

All animals were starved for 18 h before autopsy During this time they were permitted water *ad libitum* A test dose of 10 per cent glucose (350 mg/100 g body-weight) was injected intraperitoneally Animals were killed by decapitation to avoid the stress of anæsthesia Blood sugar determinations were carried out by a modification of the anthrone method of Kahan[5] for the determination of glucose using trichloroacetic acid as a serum protein precipitant

Pancreatic tissue for histological examination was fixed in either Zenker's solution or neutral formalin (Lillie), cut at 3μ, and stained with either hæmatoxylin and eosin or a modification of Gomori's aldehyde fuchsin with trichrome counterstain as described by Lazarus[6] to demonstrate alpha and beta cells in the islets of Langerhans

Islet size was determined by counting the total number of islets larger than 25μ in any one diameter, in each section, and determining the average Individual samples of pancreas were taken from 6 virgin male and 6 female control rats Separate samples of pancreas were taken from 12 male and 12 female breeder rats The measurements were made with the aid of a calibrated ocular micrometer

Comparison of the glucose tolerance curves of breeder rats with virgin control rats revealed the presence of a significant hyperglycæmia in the breeder rats (cf Tables 1 and 2) at the critical 1-h period after the introduction of a glucose load

The mean fasting blood sugar-level of female breeders was significantly lower than that shown by female virgins virgins = 114 ± 2 0 versus breeders = 91 ± 2 0 mg per cent The female breeders showed marked hyperglycæmia compared with the female virgins at the first hour, that is, breeders (43 rats) = 224 ± 8 0 versus virgins (12 rats) = 179 ± 5 0 mg per cent This condition was reversed after the second hour and all blood sugar-levels in the arteriosclerotic rats returned to levels slightly lower than the controls in the third and fifth hours No differences were seen in the glucose tolerance curves between female breeders with varying degrees of gross arteriosclerosis (Table 1)

In contrast to the female breeders, the male breeders showed significantly higher fasting blood sugar-levels than controls under similar fasting conditions (Table 2) The male breeders also showed a significantly greater glycæmia than controls at the 1-h period, that is, male breeders = 272 ± 19 0 versus male virgins = 177 ± 8 0 mg per cent

Finally, female breeders showed a significantly lower fasting blood sugar-level than male breeders, that is, male breeders = 119 ± 4 0 versus female breeders = 91 ± 2 0 mg per cent ($P = 0\ 001$) This was the reverse of the finding in fasting virgin male and female rats, that is, male virgins = 100 ± 0 5 versus female virgins = 114 ± 2 0 mg per cent ($P > 0\ 001$)

Pancreatic tissue taken from both male and female breeders showed that the islets of Langerhans were greatly increased in both size and number as compared to virgins (Figs 1 and 2) The average size of the islets sampled in the virgin female and male control rats was 138μ and 130μ, respectively The average size of the islets in female and male breeders was 160μ and 176μ, respectively Also, in breeder rats the ratio of beta to alpha cells in the islets was increased However, the beta cells were also degranulated The degree of islet hypertrophy and hyperplasia corresponded with the intensity of the arteriosclerosis That is, the largest islets were found in rats with severe arteriosclerosis The details of the histology and cytology of the islet tissue in these animals have been described in a separate publication[7]

The results of these glucose tolerance tests indicated to us that there was some defect in the carbohydrate metabolism in the repeatedly bred rats The degree of

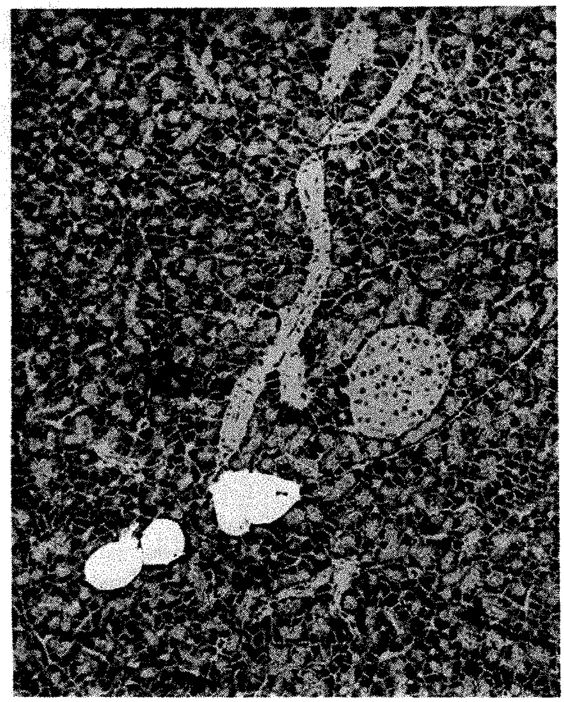

Fig. 1. Pancreas of 9-month-old female virgin rat. Note size of islet in centre of photo. Compare with giant-sized islet in Fig. 2. (Hæmatoxylin and eosin, × 90)

hyperglycæmia, however, was not markedly abnormal. This condition of hyperglycæmia would best fit the known physiological facts concerning these animals. That is, the mild hyperglycæmia would be consonant with a steroid type of diabetes, which is in keeping with the hyperadrenocorticoid condition of these animals[8-12]. In this connexion, a large percentage of patients with atherosclerosis given glucose tolerance tests are found to have a mild, stable diabetes[12]. It has frequently been suggested that there may be an ætiological connexion between carbohydrate metabolism and atherosclerosis[12-20]. A similar mechanism may be applicable to the development of atherosclerosis in the case of these breeder rats, either by virtue of their disturbed carbohydrate metabolism or because of abnormal fat metabolism which is a frequent concomitant of deranged carbohydrate metabolism.

Comparison of the glucose tolerance curves of animals with graded gross arterial pathology (female breeders) indicated that there was no relationship between the severity of hyperglycæmia with ascending degrees of arteriosclerosis ('clear' to 'severe'). The male breeders displayed a more abnormal glucose tolerance curve than the females, yet the arteriosclerosis in male breeders was mostly of microscopic proportions, rarely appearing grossly. This sex dichotomy in the severity of arteriosclerosis and hyperglycæmia in the breeder rat is interesting in that, among human diabetics, female diabetics compared with non-diabetic females show a definite increase in the appearance and severity of arteriosclerosis, hypertension, and in the incidence of myocardial infarction[13-15]. The morphology of the arterial lesions seen in breeder rats is highly reminiscent of the type of arterial lesion which is alleged to be characteristic of diabetes in the human, that is, endothelial hyperplasia, and intense accumulation of acid mucopolysaccharides[13-15].

The spontaneous nature of the mildly disturbed carbohydrate metabolism in these breeder rats resembles the diabetes seen in women during pregnancy. It is well known that latent diabetes may be unmasked during the stress of pregnancy[16-18]. This diabetic tendency has been linked with the gluconeogenic effects of the increased adrenal steroid secretion during pregnancy. Campbell and McKechnie[19], of South Africa, have found spontaneous diabetes developing in both husband and wife among Natal Indians now residing in Africa. Although the diabetes is mild, it is particularly productive of severe and lethal diabetic vascular disease. These Natal diabetics have buffalo-hump obesity, hypertension, striæ, are resistant to and are not dependent on insulin, and seldom become ketotic. The Natal diabetic females are often very hirsute. The inhabitants of Natal pride themselves in having large families, the female being kept practically in a constant state of pregnancy[20]. These workers believe that the diabetes which develops in Natal husbands and wives may be linked to parity and to the overproduction of adrenal steroids and certain sex steroids. Although it is highly speculative to suggest that the phenomena described in the Cushingoid Natal inhabitants and the hyperadrenocorticoid repeatedly bred rats are the same, none the less the similarity between the two is so striking that it is provocative and bears mention and investigation.

The heightened activity of the pituitary-adrenal system which accompanies repeated breeding in these animals could be responsible for the hyperglycæmia. This physiological interrelationship has both medical and biological counterparts. It has been amply demonstrated that administration of ACTH or the adrenal steroids can predispose towards and produce a diabetic state in the normal man or animal[11,21-24], that is, steroid diabetes. It should be borne in mind, also, that patients with Cushing's disease often have a mild diabetes accompanied by islet hyperplasia, adrenal enlargement, fatty liver and severe arteriosclerosis[15,25]. This same set of conditions has already been described in these breeder rats[1-4]. A similar syndrome of hyperadrenocorticism, islet hyperplasia, diabetes and arteriosclerosis has been described in spawning salmon[26-28] and in mice with transplanted ACTH-secreting tumours[29,30].

Finally, in separate cytological investigations of the alpha and beta cells of the islets of these breeder rats, we

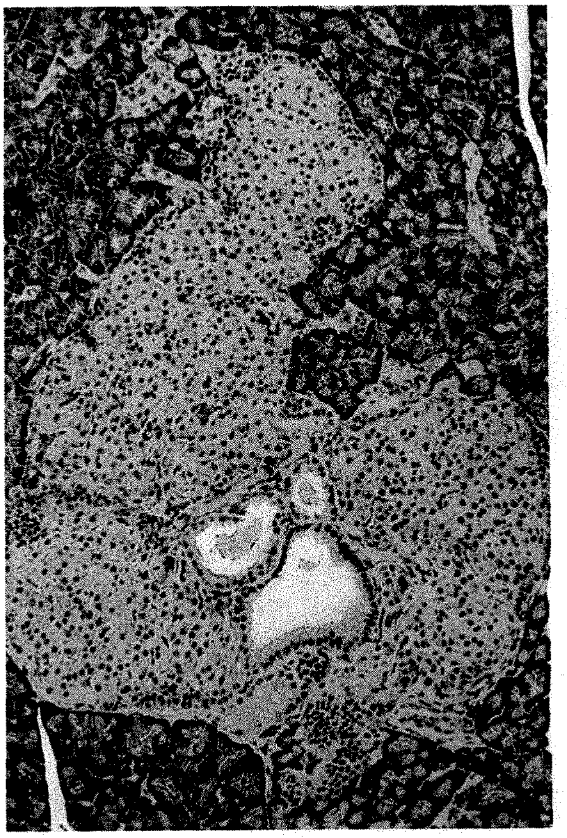

Fig. 2. Giant-sized islet in 9-month-old female breeder rat (4–5 litters). Contrast with normal-sized islet in virgin rat (Fig. 1). (Hæmatoxylin and eosin, × 90)

found that islet hyperplasia was accompanied by beta cell degranulation[7]. In addition, beta cell degranulation was more marked in the more enlarged islets. It has been suggested that the islets of Langerhans through their capacity for compensatory increase in insulin production (or functional reserve) are able to maintain normal levels of blood glucose[31]. Islet hyperplasia may be produced by the injection of ACTH or adrenal steroids and is believed to be due to increased need for insulin because of the hyperglycæmia induced by the potent gluconeogenic effects of the adrenal steroids[30-32]. When the islets lose their resiliency for increased insulin production, overt hyperglycæmia becomes evident. Thus, the vitality of the insular cells plays an essential part in offsetting diabetes[31]. It is felt that the increased adrenal activity which accompanies repeated breeding stimulates islet hyperplasia by way of response to the heightened gluconeogenic activity induced by the increased production of adrenal steroids which accompanies repeated breeding.

In conclusion, it is felt that repeated breeding leads to the development of a disturbed carbohydrate metabolism. The degree of hyperglycæmia reflected by the glucose tolerance curves indicates that the carbohydrate metabolic disturbance is of mild degree. The mildness of the hyperglycæmia, the islet hyperplasia and beta cell degranulation, and the heightened adrenal activity are believed to be indicative of a Cushingoid condition existing in these breeder rats. Future investigations will be directed towards understanding the possible connexion between the hyperglycæmia, the hyperadrenocorticism and the arteriosclerosis observed in these breeder rats.

BIOCHEMICAL EFFECTS OF X-IRRADIATION AND THE SULPHYDRYL HYPOTHESIS: A RE-APPRAISAL

By Dr. MARGERY G. ORD and Dr. L. A. STOCKEN

Department of Biochemistry, University of Oxford

THE radiosensitivity of dividing cells has been apparent from the earliest investigations of the biological consequences of X-irradiation[1]. One of the first attempts to provide a unified biochemical basis for irradiation damage was that of Barron *et al.*[2-4], who showed from experiments *in vitro* that sulphydryl (SH) groups in such compounds as cysteine, glutathione, proteins and enzymes could be oxidized as a result of exposure to X-rays, and who postulated that such an oxidation, if occurring intracellularly, would produce serious metabolic disturbances within the cell. Unfortunately many detailed investigations of SH enzymes in tissues following whole-body irradiation failed to detect any significant inhibition, so that a generalized inhibition of SH enzymes could not be established[5,6]. Since that time work on the biochemical effects of X-irradiation has been focused on the reduction in DNA synthesis[5,6], although reports have been available of reduced sulphydryl contents of tissues and nuclear extracts[7,8].

In the course of many experiments on DNA synthesis, it has been shown that the nucleus itself is directly affected by X-irradiation[9-13], and attempts have been made to find biochemical reactions associated with the nucleus which might explain its radiosensitivity. One such reaction is nuclear phosphorylation[14], and in an attempt to determine the site(s) at which X-rays interfere with nuclear generation of energy[15-17] it has been shown[18] that sulphydryl compounds present in thymus nuclei (Table 1, series 1–3) can not only be oxidized by exposure (series 4, 6, 8) but also made more reactive towards sulphydryl reagents

Table 1. SULPHYDRYL CONTENT OF THYMUS NUCLEI. SH AS MμMOLES/MG DNA PHOSPHORUS (NO. EXPERIMENTS)

Series	Time of incubation with dithiobis (2-nitrobenzoic acid) (min)	Control	Experimental
1 Nuclei isolated in ionic medium (15)	30	308	—
2 Nuclei isolated in sucrose medium (7)	5	375	—
	30	469	—
3 Nuclei isolated in sucrose and suspended in ionic medium (6)	30	632	—
4 Nuclei isolated in sucrose medium. 1,000 r. *in vivo* or *in vitro* (5)	5	381	329
5 As above, no Zn (2)	30	489	489
6 As above, with Zn (4)	30	528	421
7 Nuclei isolated in ionic medium after 1,000 r. *in vivo* (2)	30	285	351
8 Ionic medium extract from nuclei isolated in sucrose. With Zn, 1,000 r. *in vitro* (2)	30	276	214

Nuclei were isolated from thymus glands of 5 or 6 rats[18]. The sulphydryl (SH) content was measured by the method of Ellman[34] after 5 or 30 min incubation with dithiobis (2-nitrobenzoic acid). Where present, Zn^{2+} was 10^{-5} M zinc sulphate.

(series 7) The oxidation of sulphydryl groups is reversed by glutathione reductase, a normal component of the isolated nuclei, so that the fall in SH content is maintained only if glutathione reductase is inhibited by 10^{-5} M Zn^{2+} (ref 19) (series 5, 6). The increase in SH content, which has only been detected after irradiation *in vivo*, is probably due to alteration of the nucleoprotein complex and it can also be brought about in normal nuclei prepared in sucrose by suspension in a medium of increased ionic strength (series 2, 3)

Reduced glutathione was detected only in small amounts in nuclei isolated in sucrose medium and was not found in nuclei obtained in ionic medium About 70 per cent of the total SH content of the nuclei was associated with the arginine-rich histones[20], which contain small amounts of cystine or cysteine[20,21] Since sulphydryl and disulphide groups of proteins and glutathione interact[22] the lowered content of nuclear SH groups following X-irradiation will lead to the temporary formation of oxidized glutathione (GSSG) within the nucleus

As a result of these findings it seemed important to attempt to relate directly the alterations in SH content of the nuclei to the known changes in nuclear metabolism post-irradiation GSSG was used to reproduce the oxidative effects of X-irradiation on nuclear sulphydryl groups To increase the number of reacting SH groups, nuclei which had been isolated in 0 25 M sucrose/5mM calcium chloride/5mM *tris* *p*H 7 2 were suspended in ionic medium[18]

Oxidized glutathione reduced the activity of glucose-6-phosphate dehydrogenase and inhibited the formation of labile phosphate (Table 2) The mechanism of nuclear phosphorylation is still uncertain and especially its dependence on the presence of oxygen The glutathione reductase system offers a means by which NADPH can be re-oxidized but does not explain the need for oxygen Moreover, GSSG is usually present in only very small amounts within cells, so that added GSSG might be expected to increase the rate of phosphorylation if glutathione reductase was the preferred enzyme for re-oxidation of NADPH The inhibitory effect of GSSG on nuclear phosphorylation therefore suggests either that the formation of ATP in thymus nuclei is associated with an oxygen-dependent oxidation of NADPH, or that the disulphide has reduced phosphorylation by interaction with some SH groups essential for the reaction

Table 2 EFFECT OF OXIDIZED GLUTATHIONE ON REACTIONS OF THYMUS NUCLEI

Reaction	Medium	Control activity	Conc (M)	+ GSSG activity as % control
Glucose-6-PO_4 dehydrogenase[18]	*I*	1 35 ± 0 485 (12)	10^{-3}	10, 32, 46 5, 33
			10^{-4}	71, 65, 62
mμmoles NADPH/min/ mg DNA P	*S*	10 46 (2)	10^{-4}	74
Nuclear phosphorylation[18] labile phosphate	*I*	20 4	10^{-3}	36 3
formed in 30 min at 0° mμmoles/mg DNA P	*I*	19 7	10^{-3}	7 1
^{23}P incorporation into	*S*	100 (ref 35)	10^{-3}	11 4, 20 6
nuclear RNA fraction	*S*	100 (ref 36)	10^{-3}	8 0
arbitrary units			10^{-4}	13 8
Cytidylic acid	*S*	100 (ref 37)	10^{-3}	2 6

Nuclei were isolated from rat thymus gland in either ionic (*I*) or sucrose (*S*) medium[15] Reactions were performed in the presence or absence of oxidized glutathione (GSSG)

Interpretation of the experiments in which the nuclear sulphydryl content was increased by suspending the preparation in ionic medium is complicated by the specific effect which some of the ions have on nuclear metabolism Na^+ particularly is known to increase the incorporation of amino-acids into nuclear protein[14], and this effect is a likely explanation of the results (J A Smit, unpublished) on the uptake of leucine where the rate in ionic medium is about twice that of nuclei in unsupplemented sucrose medium The rate of phosphorylation by nuclei isolated in sucrose medium and finally suspended in ionic medium was not diminished Phosphorylation, therefore, is not reduced by treatment of the nuclei with ionic medium, although from the increased SH content in parallel experiments some disorganization of nuclear structure must have occurred Allfrey and his colleagues have shown[14] that, although deoxyribonuclease treatment prevents phosphorylation, protein synthesis could be restored by the addition of DNA, suggesting that radical changes in structure do not cause cessation of all synthetic functions in the nucleus

When incorporation of phosphorus-32 into nucleic acids was examined, unequivocal uptake into DNA was not obtained Incorporation into the RNA fraction was unaffected by suspending nuclei in ionic medium but was profoundly reduced by 10^{-3} M GSSG (Table 2) The effect of oxidized glutathione was confirmed by isolation from the RNA hydrolysate of cytidylic acid X-irradiation *in vivo* is known to inhibit precursor uptake into nuclear RNA in rat thymus as well as into DNA[23]

From these experiments it is clear that agents which produce alterations in the nuclear SH/SS equilibrium produce metabolic effects which are paralleled by X-irradiation The biochemical changes associated with the formation of the mitotic apparatus are not completely established, but SH/SS interactions are involved and the process is profoundly affected by exogenous SH compounds[24] The radiosensitivity of spindle formation is well known It seems possible, therefore, that the changes in sulphydryl groups which can be detected in nuclei after X-irradiation may represent a morphological change at the macromolecular level and be responsible for some of the cytological effects and for the early biochemical lesion

The importance of the glutathione reductase system in reversing the oxidative effects of X-irradiation is obvious, and the presence of this enzyme in cell fractions other than the nucleus[25] may account for the failure to detect any reduction in the activity of tissue SH enzymes after exposure In the thymus, nuclear SH groups account for about 20 per cent of the SH content of the cell, but glutathione appears to account for a comparatively small fraction of the nuclear sulphydryl compounds[18] The response of all cell fractions will presumably depend on the relative availability of glutathione reductase, NADPH and glutathione, the protection afforded by sulphydryl compounds against X-radiation damage is well established[5,26,27] It is known that mitochondrial function may also be disturbed following irradiation *in vivo*[28,29]; the role of SH groups in maintaining structure/function relationships in mitochondria has been considered[30].

While the presence of glutathione reductase may account for the difficulty in detecting changes in SH groups after irradiation, it is not certain that the original conformation of the sulphydryl groups will be restored The increase in nuclear SH groups which is detectable after X-irradiation *in vivo*, especially in nuclei isolated in ionic medium, suggests that disorientation of the nucleoprotein structure is also produced When normal nuclei are suspended in ionic medium protein loss into the aqueous phase is more marked than with suspension in sucrose medium[31] and total SH reactivity is increased Loss of nuclear catalase[12] and increased extractability of DNA[32] following irradiation *in vivo* may be correlated with the disturbance to nucleoprotein structure, and this disorganization seems likely to be irreversible and to be associated with the less-sensitive phase of the irradiation response[33]

This work was supported by the Department of Scientific and Industrial Research, the Rockefeller Foundation and the National Institutes of Health, U S Public Health Service (*A* 3369) We thank Mi A Morris and Mr P Copper for their assistance

Note added in proof The Russian workers[38] have now extended their findings on changes in sulphydryl content of rat liver nuclei after 1,500 r total-body irradiation 30 min after exposure the SH content of two nuclear protein fractions is decreased, and in a third fraction, thought to be associated with the nucleolus, the SH-level rises Their data are discussed in relation to the effects of X-irradiation on mitosis and cell division

INHIBITION OF THE AGGREGATION OF BLOOD PLATELETS BY NUCLEOSIDES

By SONIA CLAYTON, PROF G. V R. BORN and DR M J CROSS

Department of Pharmacology, Royal College of Surgeons of England, London, W C 2

ONE of the immediate causes of thrombosis is the aggregation of blood platelets It has been found that adenosine diphosphate (ADP), out of a large number of nucleotides tested, was the only one which brought about the aggregation of platelets in human plasma[1] We have used a turbidimetric method to follow the aggregation of platelets quantitatively, and shown that the aggregation induced by ADP is partially prevented by adenosine triphosphate, by adenosine monophosphate (AMP) and by adenosine, the last being much the most effective[2] It was suggested that ADP combines with specific sites on the surface of the platelets To find out more about this reaction, and because inhibitors of aggregation may prove to be of therapeutic value, we have now tested the effects of more compounds related to adenosine on the aggregation of platelets

The methods for preparing human plasma rich in platelets and for measuring their aggregation have been described previously[2] In each experiment ADP was added at a final concentration of 10^{-6} M, and the optical density of the plasma was recorded at short intervals for about 15 min When a compound was tested it was mixed with the plasma 5 min before the ADP was added and readings of the optical density were made during this period also This was done for two reasons (1) to see if the compound could itself bring about the aggregation of platelets, (2) although the inhibitory effect of adenosine increased the longer it was in the plasma, the effect was evident in less than 5 min[2]

The plasma was stored in a 'Perspex' cylinder at room temperature During the day the extent to which the platelets aggregated after adding ADP often decreased This decrease persisted even when the plasma was kept at 37° C or, at room temperature or at 37° C, in a dialysis bag suspended in Krebs solution through which was bubbled a mixture of 95 per cent oxygen and 5 per cent carbon dioxide (v/v) Because of this, the effects of inhibitors were always assessed by bracketing an experiment in which an inhibitor was present between two control experiments in which ADP alone was added

The activities of other compounds were compared with that of adenosine in the following way A concentration of adenosine (usually 5×10^{-6} M) was chosen which reduced the maximal change in the optical density brought about by ADP (10^{-6} M) by about 60 per cent The potential inhibitor was then tested at a concentration one hundred times greater than that of adenosine If it had less effect than the adenosine its activity was recorded as less than 1 per cent of that of adenosine and no further tests were made (Table 1) If, however, its activity was greater than that of adenosine a more exact comparison was made by finding the concentration of inhibitor which had the same effect as (i) 5×10^{-6} M adenosine, and (ii) 10^{-6} M adenosine In each case the activity of the compound was expressed as a percentage of the activity of adenosine, that is,

$$\frac{\text{concentration of adenosine selected for the comparison}}{\text{concentration of inhibitor required to produce the same inhibition as the chosen concentration of adenosine}} \times 100$$

Though the absolute effects of the inhibitors varied from plasma to plasma their relative activities did not alter very much This is illustrated in Fig 1, in which are compared the activities of adenosine and isoguanosine at different concentrations and in samples of plasma from three different individuals

The average of the two results for each inhibitor is shown in Table 1 They emphasize that the adenosine moiety is a very important component of the nucleosides and nucleotides which influence the aggregation of platelets The activity of adenosine as an inhibitor was considerably reduced by small changes in the purine ring itself, as in 6-amino-8-azapurine riboside, in the substituents on the purine ring, as in purine riboside, 6-methylaminopurine riboside and isoguanosine, or in the ribose fraction, as in deoxyadenosine and 6-amino-1′-hydroxymethylpurine riboside It was particularly striking that cyclic-AMP not only had less than 1 per cent of the activity of adenosine but also less than 1 per cent of the activity of AMP, with which, in one experiment, it was directly compared

Table 1 INHIBITORY ACTIVITIES OF COMPOUNDS RELATED TO ADENOSINE COMPARED WITH THAT OF ADENOSINE ITSELF

Compound	Activity % of the activity of adenosine
2-oxy, 6-amino purine riboside (isoguanosine)	5
Diphosphopyridine nucleotide (DPN)	2
6-methyl amino purine riboside	2
Flavin adenine dinucleotide (FAD)	2
Purine riboside*	Less than 1
2 6 Diamino purine riboside	
2-amino, 6-oxy purine riboside (guanosine)*	
2-oxy, 6-amino pyrimidine riboside (cytidine)*	
6-mercapto purine riboside	
6-oxy purine riboside (inosine)*	
Adenine*	
6-amino purine, 2-deoxy-D-riboside (deoxyadenosine)	
6-amino, 8-aza purine riboside (azaadenosine)	
6-amino-9-β-D-fructopyranosyl purine	
6-amino-9-α-D-fructofuranosyl purine	
6-amino-1′-hydroxymethyl purine riboside (psicofuranine)	
Adenosine 3′,5′-cyclic phosphate (cyclic AMP)	
Triphosphopyridine nucleotide (TPN)	
Ribose*	

* Tested by Born and Cross (ref 2)

Only two of the compounds tested, deoxyadenosine diphosphate (deoxy-ADP) and adenosine tetraphosphate, brought about aggregation of platelets Their activities were compared with that of 10^{-6} M ADP by finding the concentrations at which they produced the same response. Deoxy-ADP had 0 3 per cent of the activity of ADP Gaarder *et al* also found that, apart from ADP deoxy-ADP was the only nucleotide which induced aggregation and in their system its activity was exactly the same as in ours[1] Adenosine tetraphosphate had 12 5 per cent of the activity of ADP This result is difficult to interpret, as the compound is unstable and may have been broken down to ADP

The observations suggest that derivatives of adenosine are in some way bound to the platelet through the adenosine part of the molecule When ADP is bound, pyrophosphate groups are introduced at the platelet surface, these may provide bridges between one platelet and another, perhaps through the formation of complexes with calcium which is necessary for aggregation by ADP[3]

Adenosine and AMP presumably inhibit aggregation by occupying sites normally available to ADP However, neither adenosine nor AMP provide pyrophosphate groups Therefore, it might be expected that derivatives of ADP in which its pyrophosphate group was 'blocked' would act as inhibitors of platelet aggregation In fact, both DPN and FAD have inhibitory activity

The specificity of the adenosine derivatives, when compared with other nucleosides and nucleotides, is even more remarkable in view of the recent observation that 5-hydroxytryptamine and noradrenaline induce aggregation of platelets[4] We have found that adenosine inhibits aggregation by 5-hydroxytryptamine and by noradrenaline just as it does aggregation by ADP Aggregation brought about by thrombin is also inhibited by adenosine (unpublished results, see also ref 5) It is likely, therefore, that adenosine derivatives influence some fundamental step common to all these ways of bringing about aggregation of platelets

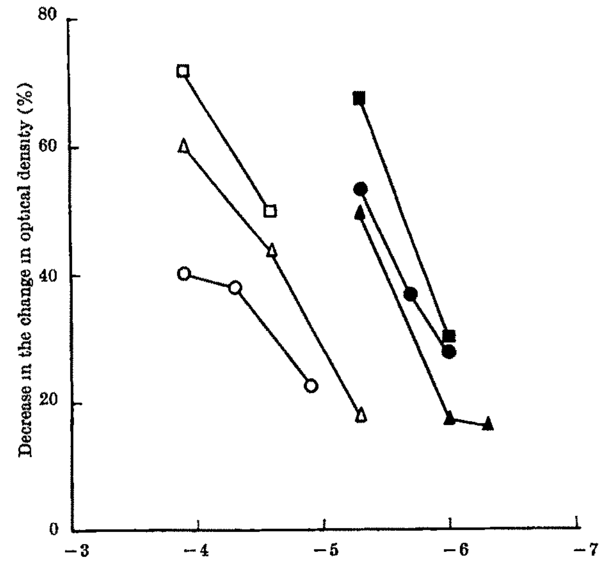

Fig 1 Relation between the logarithms of the concentrations of isoguanosine and adenosine and the inhibition of platelet aggregation Ordinate, reduction in the change in optical density expressed as a percentage of the change in optical density which followed the addition of ADP alone, abscissa, logarithm of concentration of isoguanosine (open points) and adenosine (closed points) Plasmas from three different individuals were used (□—□, △—△, ○—○) In each experiment the inhibitor was added 5 min before the addition of ADP (10^{-6} M)

We thank Dr E. Fitzgibbon for gifts of 2,6-diaminopurine riboside, 6-methylaminopurine riboside and isoguanosine, Dr E J Reist for 6-amino-9-α-D-fructofuranosyl purine and 6-amino-9-β-D-fructopyranosyl purine, Dr R B. Ross for 8-azaadenosine, and Dr R E Handschumacher for psicofuranine. DPN, TPN, FAD, 6-mercaptopurine riboside, deoxyadenosine, and cyclic-AMP were supplied by the Californian Corporation for Biochemical Research, Los Angeles We also thank members of the staff of the Equity and Law Life Assurance Society, Ltd , who voluntarily gave blood

IN VITRO EFFECT OF SALICYLATE ON AMINO-ACID ACCUMULATION BY KIDNEY CORTEX SLICES

By Dr STANTON SEGAL and ALBERTA BLAIR

Clinical Endocrinology Branch, National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Bethesda, Maryland

ANDREWS *et al* [1] contributed to our knowledge of the biochemical changes in salicylate intoxication with the finding of amino-aciduria in several affected patients Because of increased amounts of urinary cystine, they postulated the mechanism to be due to 'overflow' of plasma amino-acids elevated as a result of salicylate-induced liver damage Their hypothesis received support with the later observation of elevated serum α-amino-nitrogen levels in these patients[2] Later, Elliott and Murdaugh[3] demonstrated that the oral ingestion of 1 6 g of acetylsalicylic acid by normal subjects increased urinary amino-acid excretion two-fold, the increase representing a generalized amino-aciduria Although the latter investigators did not measure plasma amino-acids, they suggested that salicylate produced a defect in tubular transport by interfering with oxidative metabolism Amino-aciduria has also been observed in salicylate-intoxicated rats[4]

It is known that amino-acids labelled with carbon-14 are actively accumulated against a concentration gradient in rat kidney cortex slices, and that the processes involved are dependent on oxidative metabolism and conform to Michaelis–Menten kinetics[5] This, therefore, seemed an appropriate system in which to ascertain whether a direct effect of salicylate on the kidney tubular cells might explain the salicylate-induced amino-aciduria This report presents results concerning the influence of this drug in the rat kidney slice system. In addition, results are presented of investigations performed using human kidney tissue obtained at surgery

Male Sprague–Dawley rats weighing 120–160 g were used in all experiments and were fed a 'Purina' chow diet and water *ad libitum* until killed by stunning and decapitation The techniques utilized for the preparation of kidney cortex slices, aerobic incubation in Krebs–Ringer bicarbonate buffer, *p*H 7 4 at 37° C and assessment of intracellular accumulation of the labelled amino-acids have been described previously[5] The concentrative uptake of amino-acid has been expressed as a distribution ratio which is expressed

$$\text{distribution ratio} = \frac{\text{counts/min/ml intracellular fluid}}{\text{counts/min/ml medium}}$$

and reflects the ratio of the concentration of amino-acid inside to that outside the cell A distribution ratio higher than one indicates concentration against a gradient and generally indicates an active transport process

All radioactive samples were counted in a liquid scintillation spectrometer at 57 per cent efficiency Ninety-minute incubations were carried out except when noted Sodium salicylate, as well as the radioactive amino-acids, were obtained commercially All amino-acids were chromatographically pure After incubation, aliquots of the boiled aqueous tissue extract of the slices were chromatographed and more than 90 per cent of the radioactivity was recovered at the appropriate R_F for the specific amino-acid investigated

The distribution ratios obtained in rat kidney slices for the several amino-acids tested are shown in Table 1 A concentration of 40 mg per cent salicylate was used since this approximated the blood levels of salicylate-intoxicated children shown to have amino-aciduria Salicylate significantly inhibited the accumulation not only of the model amino-acid α-amino-isobutyric acid (AIB), but also that of the natural amino-acids, glycine, L-phenylalanine, L-histidine and L-lysine This concentration of the drug had no influence on the size of the inulin space, 25 7 ± 1 1 per cent of the wet tissue weight[6], or the amount of total tissue water, 80 2 ± 1 per cent of the wet tissue weight

Table 1 EFFECT OF SALICYLATE ON ACCUMULATION OF AMINO-ACIDS BY RAT KIDNEY CORTEX SLICES

	Distribution ratio		
	Control	Salicylate 40 mg %	*P*
AIB (0 065 mM)*	4 45 ± 0 31† (13)	2 70 ± 0 17 (13)	< 0 001
Glycine (0 015 mM)	9 10 ± 1 15 (4)	5 25 ± 0 86 (4)	< 0 05
L-phenylalanine (0 15 mM)	2 72 ± 0 32 (4)	1 67 ± 0 11 (4)	< 0 05
L-histidine (0 035 mM)	2 75 ± 0 13 (6)	1 65 ± 0 07 (6)	< 0 01

No of determinations in brackets

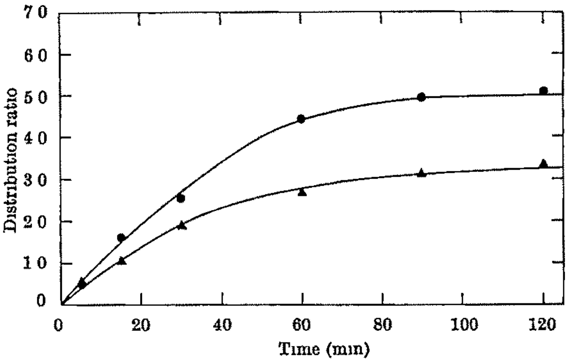

Fig 1. The effect of salicylate on the accumulation of AIB by rat kidney cortex slices ●, Control, ▲, salicylate, 40 mg per cent

The values obtained for distribution ratio after ninety-minute incubation (Table 1) represent the accumulation by the cells after a steady state has been reached[7] That is, the distribution ratio is at a constant level dependent on the relation of the rate of entry of the amino-acid into the cell and the rate of egress from the cell To demonstrate the findings prior to attainment of the steady state, the effect of salicylate on the time course of accumulation of α-amino-isobutyric acid (AIB) is shown in Fig 1 Each time point represents paired data obtained from three different animals It may be observed that the salicylate has an inhibitory effect on the accumulation as measured by the distribution ratio after fifteen minutes of incubation, with the attainment of a final distribution ratio about 35 per cent lower than the control

Data such as shown in Fig 1 may be analysed kinetically, using the mathematical model approach of Rosenberg, Berman and Segal[7] We have thus determined the fractional rate of influx and efflux of AIB for the kidney slice as influenced by salicylate The fractional rate constants were 0 00247 min^{-1} and 0 0216 min^{-1} for influx and efflux respectively in the controls The values were 0 00192 min^{-1} and 0 0294 min^{-1} for influx and efflux respectively for the salicylate-treated tissue This represents a 22 per cent decrease in influx and a 36 per cent increase in efflux fractional rate constants According to this analysis, the effect of salicylate is to decrease the transport of amino-acid into the cell while at the same time accelerating the rate at which the amino-acid already accumulated leaves the intracellular pool and returns to the medium

Salicylate was found to have an inhibitory effect on accumulation of amino-acid by rat kidney cortex slice at drug concentrations lower than 40 mg per cent, a significant inhibition being found at a concentration of 10 mg per cent At 20 mg per cent the inhibition appeared to be maximal with little further inhibition beyond this point up to the 80 mg per cent investigated An attempt was made to overcome the inhibition of amino-acid accumulation caused by salicylate by the addition of various substrates to the incubation buffer None of the following compounds at 5 millimolar levels were able to accomplish this glucose (90 mg per cent), pyruvate, fumarate and acetate

The salicylate-induced defect in amino-acid accumulation was also present when rat hemidiaphragm was investigated No such effect could be induced, however, in rat small-intestinal segments, using glycine as the test amino-acid With regard to the structural specificity of the salicylate molecule to produce its effect, we were unable to show a similar inhibition with the isomer *p*-hydroxybenzoic acid

Slices of human cortex weighing 5–20 mg were examined in a fashion identical to that utilized for the rat using a single 90-min incubation point The results are shown in Table 2 The effect of salicylate in human tissue paralleled that in rat tissue and caused a decreased intracellular accumulation of amino-acid in each of the patients examined Cystine was included in the experiment in one patient to see if the cystinuria seen in salicylate intoxication could be reflected in a direct kidney action of the drug

Table 2 ACCUMULATION OF AMINO-ACIDS BY HUMAN KIDNEY CORTEX SLICES

	Distribution ratio

* 40 mg per cent
† Each value is an average of triplicate determinations.

The physiological mechanism of the salicylate effect on amino-acids appears to be an inhibition of transport of the amino-acid into the cell and prevention of maintenance of the intracellular amino-acid pool by causing an acceleration of the loss of amino-acid from the pool The biochemical effect can only be speculated on. The similarity of the effect of salicylate to the effect of metabolic inhibitors such as dinitrophenol[7] and maleic acid[8] in the same kidney slice system prompts the suggestion, similar to that of Elliott and Murdaugh[3], that salicylate interferes with the oxidative metabolism so vital to the formation and maintenance of intracellular amino-acid pools[5] That salicylate uncouples oxidative phosphorylation has been well established[9]

The conclusion by Andrews *et al* [1] that the amino-aciduria of salicylate intoxication is entirely explainable as an 'overflow' phenomenon does not seem to be entirely justified Their conclusion was partly based on the presence of cystine in the urine We have shown that salicylate can interfere with cystine accumulation (Table 2) The present findings recorded here suggest that a major factor in salicylate-induced amino-aciduria, though perhaps not the sole factor, is a direct effect of salicylate on the renal tubule, causing a decreased reabsorption of filtered amino-acids The recently reported shedding of renal tubular cells caused by salicylates in humans[10] indicates that a structural alteration may be induced in the tubule The association of the latter phenomenon to the amino-aciduria is open to speculation

PHYTOHÆMAGGLUTININ: SEPARATION OF HÆMAGGLUTINATING AND MITOGENIC PRINCIPLES

By Dr. P. BARKHAN and Dr A. BALLAS

Medical Research Council Experimental Hæmatology Research Unit, Wright-Fleming Institute, and Department of Hæmatology, St Mary's Hospital Medical School, London, W 2

THE existence of hæmagglutinins (phytohæmagglutinins) in the seeds of some plants, particularly Leguminosae, has been known for many years[1,2] Li and Osgood[3] used an extract of red kidney beans (*Phaseolus vulgaris*) to sediment red cells and then isolate leucocytes for culture Later, Rigas and Osgood[4] described a method for the preparation and concentration of the bean phytohæmagglutinin (PHA) Nowell[5] then made the important discovery that PHA induced mitosis in human peripheral blood leucocytes, and his observation led to the development of a simple culture method which has been widely used for the examination of human chromosomes The cellular and biochemical changes in the leucocytes cultured with PHA have been examined by Cooper, Barkhan and Hale[6,7], Carstairs[8], Elves and Wilkinson[9] and Quaglino, Hayhoe and Flemans[10] It seems that PHA induces synthesis of DNA in the lymphocyte population of the leucocyte cultures Enlargement of certain lymphocytes with morphological transformation to cells that resemble blast cells is a striking feature of these cultures These transformed cells then undergo mitosis

It is of fundamental interest to know more about the plant mitogen and how it works, since this information may be valuable during investigations on the general problem of cellular proliferation An important preliminary step is to find out whether the hæmagglutinating activity is separable from the mitogenic activity In this communication we present evidence which favours the existence of two separate principles

Normal venous blood obtained from clinically healthy subjects was mixed with preservative-free heparin (0 25 mg heparin/ml. blood) The container was then centrifuged at 1,500 r p m for 10 min and about 0 5 ml buffy coat was removed and set aside in a separate bottle containing culture medium *TC* 199 The leucocytes in this buffy coat suspension were used for culture (see following) To the remainder of the blood 0 2 ml (2 mg) PHA was added The blood and PHA were carefully mixed and then left to stand at room temperature for 30–60 min Thereafter the container was centrifuged at 3,500 r p.m. for 20 min The supernatant cell-free plasma (3–4 ml) was then removed, great care being taken not to disturb the buffy coat This plasma was then well mixed with a fresh volume of red cells from which the plasma had been removed by prior centrifugation After standing for 30–60 min at room temperature the bottle was centrifuged at 3,500 r p m for 20 min and the supernatant plasma was carefully removed The plasma was then absorbed a third time with fresh red cells This thrice-absorbed plasma was added to the buffy coat suspension to produce a leucocyte concentration of 0 5–1 million cells/ml , the total volume of the culture was about 10 ml and the plasma concentration was 25–50 per cent The culture was incubated at 37° C for about 65 h Colchicine to a final concentration of 10^{-6} M was then added to the culture, which was incubated for a further 2 h. Thereafter the bottle was centrifuged and a drop of the cellular deposit was mixed with a drop of 1 per cent orcein in 45 per cent acetic acid and overlaid with a coverslip This preparation was examined for cell transformation and mitotic activity

The agglutinin titre was estimated by a tube method, using a 5 per cent suspension of red cells in normal saline

The phytohæmagglutinin was prepared from red kidney beans (*Phaseolus vulgaris*) at the Wellcome Research Laboratories, Beckenham, England The dry material was dissolved in normal saline to a concentration of 10 mg/ml

Removal of agglutinin Group A, B and O red cells were equally well agglutinated by the PHA preparation, and it was assumed, therefore, that they adsorbed the PHA equally well

Most of the agglutinating activity of the PHA was removed from the plasma by the first absorption with red cells (titre reduced from 1 32 to 1 · 4) The second absorption removed most of the remaining agglutinins (agglutination present only in undiluted plasma) After the third absorption plasma samples still showed a trace of agglutinating activity Even with six absorptions careful examination showed that traces of agglutinin remained Three absorptions removed more than 95 per cent of the original agglutinating activity

Cell transformation and mitotic activity The cultures prepared with absorbed plasma showed excellent cell transformation and mitotic activity (Fig 1) In terms of these two parameters they were at least as active as the

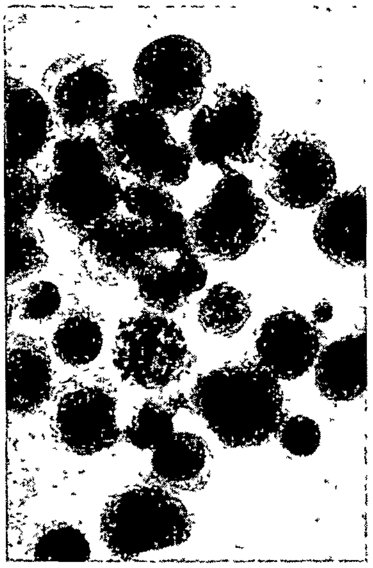

Fig. 1. Photograph of transformed cells and mitoses in a leucocyte culture prepared with PHA in plasma after absorption with red cells. The culture was treated with 0·5 per cent sodium citrate to partially separate the chromosomes in the dividing cells. The photograph shows two cells in metaphase (× 800)

control cultures which were set up with plasma and 0·2 ml PHA. Equally good results were obtained with A, B and O group blood. In drawing off the buffy coat for culture, relatively large numbers of red cells accompanied, and, in fact, outnumbered the leucocytes. The homogeneous unagglutinated appearance of the red cell suspension in the 'absorbed' culture was a striking macroscopic and microscopic feature and contrasted sharply with the control which showed gross red cell agglutination. These appearances persisted throughout the culture period.

Absorption from culture medium. During the course of this investigation it was found that if PHA was added to *TC* 199 medium a single absorption with washed red cells was sufficient to remove all the agglutinating activity, that is, in the absence of plasma the agglutinin was more easily removed. This agglutinin-free absorbed supernate produced both cell transformation and mitoses. Although these changes were less marked than those found with absorbed plasma, they were clearly evident and unequivocal.

Electrophoresis of PHA. We have attempted to separate the mitogenic and agglutinating principles by starch block electrophoresis (barbital buffer, *p*H 8·6, ionic strength 0·05). Agglutinating activity was found on the cathodal side of the origin in a zone stretching between and overlapping the β- and γ-globulin bands of the human plasma marker. However, none of the fractions showed mitogenic activity.

The PHA was electrophoresed on cellulose acetate paper (barbital buffer *p*H 8·6, ionic strength 0·05) which was then stained with ponceau *S*. Three bands were seen: two major ones corresponding in mobility to γ-globulin and a minor one with the mobility of α-2-globulin of the human plasma marker.

This investigation shows that agglutinating activity can be removed from PHA without loss of the mitogenic factor. It would seem, therefore, that the agglutinating and mitogenic activities are different entities. The removal of the agglutinin by absorption with red cells offers a simple and rapid way of separating the two principles. Although it is difficult to remove the last traces of agglutinating activity from plasma, removal is complete from culture medium.

Punnett and Punnett[11] have attempted to separate the mitogen (leucocyte growth factor) from the agglutinin with the use of a rather drastic and extensive chemical fractionation procedure. They concluded that either the growth factor and agglutinin are different molecules or separable portions of one macromolecule. However, they pointed out that the preparative procedure used was so extensive that it was not possible to distinguish between these two possibilities, and stated that it would not be certain that the leucocyte growth factor and phytohæmagglutinin are different components until a less-drastic procedure has been worked out. Absorption with red cells is probably the least-drastic procedure for this kind of separation. Another point in favour of two different substances is the result of fractionation by starch-block electrophoresis, which is also a relatively mild procedure; agglutinating activity was easily recovered, but the mitogenic activity appeared to have been lost. Failure to recover the mitogen might have been due to its intrinsic instability under the conditions used, or to dissociation from an active complex or to very fast migration causing it to run off the block. Thus, after absorption with red cells, mitogenic activity could be obtained with little or no agglutinating activity, and after starch-block electrophoresis agglutinating activity could be found without mitogenic activity.

It has recently been reported that tuberculin[12] and diphtheria toxoid[13] are mitogenic in leucocyte cultures from appropriately immunized subjects. Their mitogenic activity appears to be similar to that of phytohæmagglutinin, but, so far as is known, neither of these substances has hæmagglutinating activity. These findings show that hæmagglutinating activity is not a necessary requirement for mitogenic activity.

When PHA was put into *TC* 199 medium, which was then adsorbed with washed red cells, mitogenic activity persisted although the agglutinin was completely removed. However, there seemed to be less mitotic activity than that found with the absorbed plasma, and this would suggest that some mitogen and agglutinin were removed together. Nevertheless, it was quite clear that mitogenic activity was still present in the complete absence of agglutinating activity. It might be argued that the mitogenic activity of the absorbed plasma was dependent on the remaining trace of agglutinating activity. While this argument cannot be directly refuted at present, we have found that certain batches of commercial phytohæmagglutinin preparations (obtained from abroad) possess no mitogenic activity, although they have agglutinating activity which is greater than that present in the adsorbed plasma.

TC 199 medium is a synthetic, non-protein mixture which is clearly very different, both chemically and physically, from plasma. It may therefore be that the conditions for absorption of PHA from plasma and from *TC* 199 medium are different, and that this could produce both quantitative and qualitative differences in the effects of absorption. Two explanations might be considered: mitogen complexes with some component in plasma, which prevents its adsorption by red cells, or mitogen reacts with one or more constituents in *TC* 199 medium which allows partial adsorption on to red cells. An attempt is being made to investigate these possibilities.

We thank Prof. P. L. Mollison for his advice. This work was supported in part by a grant to one of us (P. B.) from the Endowment Fund of St. Mary's Hospital. A. B. was supported by a bursary from the British Council.

EARLY EFFECTS OF GLUCOCORTICOIDS ON PRECURSOR INCORPORATION INTO GLYCOGEN

By Prof HAROLD L SEGAL and Miss CONCEPCIÓN GONZÁLEZ LÓPEZ

Department of Pharmacology, St Louis University School of Medicine, St Louis 4, Missouri

THE activity in liver of a number of enzymes concerned with amino-acid metabolism has been shown to be increased consequent to administration of glucocorticoids to the whole animal These include tryptophan pyrrolase[1], glutamic-tyrosine transaminase[2], and glutamic-alanine transaminase[3] The first two of these reach a peak of activity a few hours after hormone administration, while the last increases in activity more slowly, requiring about five days to reach a maximum The question has been raised whether the increases in activity of these enzymes are causally related to the glucocorticoid-induced increase in glycogen synthesis Although the elevation in liver glycogen content in starved animals is clearly evident about four hours following hormone administration[4,5], it is not known whether all precursors flow into glycogen at an accelerated rate according to the same time sequence, or whether there is a stimulation in the conversion of diverse precursors into glycogen each according to a characteristic time course, perhaps as a consequence of the induction of separate enzyme activities A decision on this point would be expected to have a bearing on considerations of the mechanism whereby the glucocorticoid-induced increase in glycogen synthesis is brought about

As an approach to this question the incorporation of labelled alanine, pyruvate, glutamate, fructose and glucose into liver glycogen has been measured in normal rats and in rats treated 2 h previously with prednisolone acetate The results are presented in Table 1 It can be seen that in the period from 2–3 h after hormone administration there was a marked increase in the incorporation of all the precursors examined into glycogen, all to about the same extent

Since there is little or no detectable change in the activity of liver glutamic-alanine transaminase until several days after glucocorticoid administration[3]; it can be concluded that the glucocorticoid-induced alterations in the activity of this enzyme do not account for the prompt increase in the conversion of alanine into glycogen noted here In further support of this conclusion, in rats pre-treated with prednisolone acetate for five days, in which liver glutamic-alanine transaminase was elevated 3–5-fold, there was no further augmentation in alanine incorporation over that found under the conditions described in Table 1

Table 1 EFFECT OF PREDNISOLONE ON THE INCORPORATION OF PRECURSORS LABELLED WITH CARBON-14 INTO LIVER GLYCOGEN

Precursor	C p m in glycogen per g liver per 10^6 c p m injected* *N*	*P*	*P/N*
Alanine	139 ± 56 (7)	1,270 ± 289 (8)	9 2
Pyruvate	43, 56	359, 366	—
Glucose	129 ± 27 (10)	1,008† ± 162 (8)	7 8
Fructose	284 ± 74 (6)	2,004 ± 371 (6)	7 2
Glutamate	27, 88	1,163, 664	—
Metabolite	Concentration *N*	*P*	
Glycogen (mg/g liver)	45 1 ± 3 3 (29)	51 3 ± 4 4 (29)	
Glucose 6-phosphate (μmoles/g liver)	0 607 ± 0 029 (10)	0 796 ± 0 059 (8)	

200–250 g male rats were injected with 1 8–13 0 × 10^6 c p m of the compound shown They were killed by decapitation and a portion of the livers dropped into hot 30 per cent potassium hydroxide 1 h later for glycogen isolation Another portion was homogenized in perchloric acid for determination of glucose-6-phosphate with the use of glucose-6-phosphate dehydrogenase Glycogen was isolated and prepared for counting as described by Hassid and Abraham[6] Chemical assay of glycogen was by the anthrone method[9] Data are expressed as means ± the standard error, except for pyruvate and glutamate where each number is an individual measurement The number in parentheses below each mean value is the number of animals in the group *N* refers to normal animals *P* refers to animals injected subcutaneously with 2 mg of prednisolone acetate 2 h previous to administration of the labelled precursor * Corrected for self-absorption † In addition to the values represented in this calculation, 3 animals exhibited little or no increase in glucose incorporation consequent to prednisolone administration (97, 75, and 164 per cent of normal, respectively)

The results in Table 1 suggest that a reaction common to the pathways of conversion of all the precursors into glycogen is stimulated after administration of the glucocorticoid Recently, Hilz *et al* [7] reported a marked elevation in the glucose-6-phosphate levels of starved, adrenalectomized rats within a few hours after glucocorticoid administration, and drew the conclusion that the increase in glucose-6-phosphate levels was a primary effect of the hormone, leading to an increase in the rate of the glycogen synthetase reaction, on which the increase in glycogen formation was dependent However, in our experiments, under conditions where a several-fold increase in incorporation of precursors into glycogen was obtained in fed rats, there was little change in the liver glucose-6-phosphate concentration (Table 1) (Livers of fed adrenalectomized rats contained as high a level of glucose-6-phosphate as did those of fed normal animals, and glucocorticoid administration, as with the normals, had little effect on this parameter On the other hand, in livers of animals deprived of food for 17 h, the glucose-6-phosphate levels fell to values more than an order of magnitude less than those in fed animals, and glucocorticoid administration in this case produced a detectable increase within 2 h, as reported by Hilz *et al* [7] An important factor in the effect of starvation on the liver glucose-6-phosphate levels is probably the marked decrease in liver glucokinase activity under these conditions, as recently reported by Viñuela *et al* [8] In our experiments, prednisolone acetate administration 2 h prior to killing produced no effect on liver glucokinase activity in either fed or starved animals, although the levels in the latter were about 0 25 those in the former, as expected from the data of Viñuela *et al* [8] Administration of the hormone was also without effect on the activities of glucose-6-phosphatase and glucose-6-phosphate dehydrogenase under these conditions) It is possible that there are two pools of glucose-6-phosphate, a relatively small one in the pathway of glycogen synthesis and a second one in the pathway of glycogen breakdown An increase in the pool in the synthetic pathway might be masked in the fed animals, where the pool from glycogen breakdown is large, but apparent in starved animals, where the latter pool has all but disappeared

It would be useful to determine whether modification of the rate of synthesis of relevant enzymes is involved in the glucocorticoid control of glycogen synthesis Puromycin inhibited the hormonal stimulation of alanine incorporation into glycogen (Table 2). However, the results are somewhat ambiguous since the level of glycogen was also greatly reduced by puromycin administration, as previously reported by Hofert *et al* [10] On the basis of the rapidity of the puromycin effect, these workers have

Table 2. EFFECT OF PUROMYCIN AND PREDNISOLONE ON THE INCORPORATION OF ALANINE INTO GLYCOGEN AND PROTEIN

Compound injected	Glycogen		Protein	
	c.p.m./g liver per 10^6 c.p.m. injected	mg/g liver	c.p.m./g liver per 10^6 c.p.m. injected	mg/g liver
None (7)	168 ± 57	41.7 ± 5.7	1,810 ± 155	169 ± 7
Puromycin (5)	42 ± 8	12.2 ± 2.2	390 ± 109	170 ± 7
Prednisolone (7)	1,540 ± 320	43.9 ± 6.0	2,070 ± 350	161 ± 5
Prednisolone + puromycin (6)	76 ± 37	7.3 ± 1.4	295 ± 58	167 ± 8

Counting and assay of glycogen, timing of prednisolone and alanine administration, and expression of data are as described in Table 1. Puromycin dihydrochloride was injected intraperitoneally in 15 mg doses 3, 2, and 1 h before killing. For protein counting and assay, a portion of liver was homogenized in trichloroacetic acid, the sediment washed with alcohol-ether and hot trichloroacetic acid and dissolved in formic acid. An aliquot was plated for counting and another aliquot evaporated to dryness for protein assay by the method of Lowry *et al.*[9] All counts were corrected for self-absorption. Number in parentheses is the number of animals in the group. There is some overlap in the individual measurements from which means were calculated in Tables 1 and 2.

concluded that the reduction in glycogen-level cannot be accounted for primarily on the basis of even a complete block of glycogen synthesis, and therefore appears to indicate a stimulation of glycogen breakdown. Thus the lower level of counts from alanine appearing in glycogen may reflect an acceleration of the breakdown of newly-formed glycogen, rather than, or in addition to, a decrease in the rate of incorporation. (This ambiguity also exists in the interpretation of the data of Greengard *et al.*[11], who found that liver glycogen-levels in starved rats administered cortisone six hours before killing were greatly reduced when puromycin was also given.) The exceedingly short time interval between the administration of the hormone and the effect observed on precursor incorporation noted here would also appear to be an argument against modification of protein synthesis as an important factor.

The results in Table 2 also permit an assessment of the possible role of increased transport into the liver as a factor in the stimulation of precursor incorporation into glycogen. As can be seen from col. 3, there was at best only a minor effect of the hormone on the incorporation of alanine into protein, of the order expected from the results of Noall *et al.*[12] on the effect of glucocorticoids on α-aminobutyrate transport in liver. If a single pool of amino-acids exists as a precursor of both protein and glycogen, this result seems to rule out increased transport as a significant factor, at least in so far as alanine incorporation is concerned.

If the activity of an enzyme controlling the rate of conversion of precursors into glycogen is affected by the administration of glucocorticoids, it might be expected that the increased incorporation would be demonstrable in liver homogenates from hormone-treated animals. However, a two-hour previous administration of prednisolone acetate was without effect on the incorporation of alanine or pyruvate into glycogen in homogenates in our experiments thus far.

The primary site of action of glucocorticoids in their stimulatory effect on glycogen synthesis still eludes definition. The marked increase in the flow of precursors into glycogen reported here precedes the increase in glycogen-level and is the earliest effect of glucocorticoids on glycogen synthesis yet observed. The fact that precursors which enter the pathway of glycogen synthesis both at the 3-carbon-level and at the hexose-level are affected indicates that the site of stimulation is at a step late in the sequence. The rates of a number of the reaction steps of glycogen metabolism are under the complex control of components of the catalysed reaction as well as other compounds present in liver[13,14]. It may well be that the key to the glucocorticoid effect on glycogen formation lies in the interaction of the hormone with these control systems.

ACIDIC POLYSACCHARIDE ANTIGENS OF A NEW TYPE FROM *E. COLI* CAPSULES

By IDA ØRSKOV and FRITS ØRSKOV

International Escherichia Center, Statens Seruminstitut, Copenhagen

AND

BARBARA JANN and KLAUS JANN

Max-Planck-Institut fur Immunbiologie, Freiburg-Zahringen

DURING recent years, Westphal and Luderitz, in collaboration with Kauffmann, have carried out extensive immunochemical analyses of polysaccharide antigens from various genera of Enterobacteriaceae[1-3]. As a logical continuation of these studies, during the past two years, in our laboratories in Freiburg and Copenhagen a more detailed examination of cell-wall and surface antigens of many *Escherichia* strains was undertaken. Until now, about one hundred serologically classified *E. coli* strains have been extracted and analysed. In earlier communications[1-3] the main emphasis was placed on the lipopolysaccharides (*O antigens*) of *Salmonella* serotypes. It is known that many *E. coli* strains carry *K antigens* in addition to their specific O antigen. We therefore extended our studies to include capsular antigens also. Results of the analysis of the sugar constituents of *Escherichia* O antigens (see also ref. 4) will be published later. In this article a new type of acidic polysaccharides corresponding to known *E. coli* K antigens is described. From two *E. coli* strains these polysaccharides were isolated, purified and analysed. By routine analysis of extracts, acidic polysaccharides were found to be present in about 20 per cent of all investigated *E. coli* strains.

The first acidic polysaccharide was isolated from strain *RVC* 2907(0141 *K*85 *ab→ac H*4). The notation of the K antigen of *RVC* 2907 as *K*85*ab→ac* indicates that quite frequently this strain splits off colonies which agglutinate in *K*85*ac* and not in *K*85*ab* serum. Changes in the opposite direction from *K*85*ac* to *K*85*ab* have not yet been observed. The common factor *K*85*a* is only poorly developed. It is possible to produce pure factor sera corresponding to the factors *b* and *c*. The K antigen of this strain was designated as a B antigen, even though it was found to be more thermo-resistant than ordinary B antigens. With respect to thermostability it should be placed between the A and B types of *E. coli* K antigens[5]. The second acidic polysaccharide originates from strain *A*295*b*(08 *K*42(*A*) —), which is the test strain for *E. coli* K antigen 42. This K antigen belongs to the A type which renders the parent strain inagglutinable in 08 serum in the living state, but also after boiling for 1 h. Two hours at 120° C will render it agglutinable to some extent in the homologous O serum.

E. coli strains were grown on ox heart infusion agar and the acetone-dried bacteria were extracted with 45 per cent phenol at 65° C for 5 min (ref. 6). The aqueous phase was dialysed, concentrated and ultracentrifuged at 105,000*g* to give a sediment of the high molecular weight lipopolysaccharide (O antigen). The supernatant was freeze-dried and the resulting material dissolved in 0·25 molar sodium chloride. Addition of 'Cetavlon'[7,8] led to the precipitation of nucleic acid–'Cetavlon' salts which were removed by centrifugation. By dilution of the supernatant with water the acidic polysaccharide was precipitated as the 'Cetavlon' salt. After separation by centrifugation the 'Cetavlon' salt was transformed into the sodium salt which was dissolved in water. By ultracentrifugation at 105,000*g* trace amounts of lipopolysaccharide, carried along with the procedure, were removed as sediment. After freeze-drying of the supernatant the purified acidic polysaccharide was obtained as a white powder. Recently, Srivastava and Adams[9,10] have applied a similar procedure for the isolation and purification of acidic polysaccharides from *Serratia marcescens*.

The procedure, when applied to *E. coli RVC*2907(0141 *K*85(*B*) *H*4) and to *E. coli A*295*b*(08 *K*42(*A*) —), yielded 5·5 and 7·8 per cent of purified acidic polysaccharide respectively. The substances dissolve slowly in water to give clear and viscous solutions, with $[\alpha]^{25}_{5461} = +\ 9{\cdot}4°$ and + 93·5° respectively.

The acidic capsular polysaccharide obtained from *E. coli RVC*2907(0141 *K*85(*B*) · *H*4) sediments in the ultracentrifuge as a homogeneous band. From the sedimentation constant of $s_{20} = 3{\cdot}5\ S$ and the diffusion constant of $D_{20} = 2{\cdot}6$ cm^{2}sec^{-1}, a molecular weight of approximately 100,000 is calculated for the polysaccharide. Its main constituents are mannose (33 per cent), rhamnose (18 per cent), glucuronic acid (19 per cent) and glucosamine (17 per cent). In addition the following radicals were found: *O*-acetyl (4 per cent), *N*-acetyl (4 per cent) and *N*-acyl (6 per cent, calculated as β-hydroxy-myristic acid). Hydrolysis with 0·25 N sulphuric acid at 100° C for 45 min liberates *N*-acetyl glucosamine and a hitherto unidentified *N*-acyl glucosamine. Chromatographic investigation of hydrolysates of the acidic polysaccharide revealed a fatty acid which could not be differentiated from β-hydroxy-myristic acid. But the isolated *N*-acyl glucosamine was chromatographically distinct from synthetic (D,L)-*N*-β-hydroxy-myristinoyl-D-glucosamine[11]. This indicates that the polysaccharide contains an *N*-acyl glucosamine not identical with, but very closely related to, *N*-β-hydroxy-myristinoyl-D-glucosamine.

The lipopolysaccharide (O antigen) isolated from *E. coli RVC*2907(0141 *K*85(*B*) · *H*4) is composed of glucosamine, heptose, galactose and glucose, thus belonging to chemotype I (ref. 1). It should be noted that in the lipopolysaccharide and in the acidic polysaccharide, glucosamine is the only common sugar constituent, whereas heptose, galactose and glucose are found in the lipopolysaccharide, and mannose, rhamnose and glucuronic acid are present in the acidic polysaccharide only. With the acidic polysaccharide all tests for galactose and/or glucose were practically negative, indicating that it contains, if any, less than 2 per cent of contaminating lipopolysaccharide. The *E. coli RVC*2907 strain, therefore, produces two polysaccharides of very different composition.

Hydrolysis of the acidic polysaccharide with N sulphuric acid at 100° C for 3 h gave rise to an aldotriuronic acid, $[\alpha]^{25}_{5461} = +\ 4°$, consisting of two mannose and one glucuronic acid residues, mannose being at the reducing end. The trisaccharide was isolated by preparative paper chromatography in 12 per cent yield (based on the acidic polysaccharide). Apart from the removal of *O*-acetyl groups, the acidic polysaccharide is stable in aqueous alkali. Periodate oxidation of the polysaccharide results in the uptake of 0·35 moles of oxidant and the liberation of 0·1 mole of formic acid per mole of anhydrohexose. The formation of formaldehyde is negligible. During periodate oxidation all the rhamnose, 55–60 per cent of the glucuronic acid and about 20 per cent of the glucosamine are destroyed. Mannose is resistant to oxidation.

An acidic polysaccharide with the same composition has been isolated from strain *D*295(0141 *K*85*ac H*4), which is a K antigen mutant isolated from *RVC*2907, and also from *CG*9, which is a wild-type strain serologically identical with *D*295 but of independent origin.

The acidic polysaccharide obtained from *E. coli A*295*b*(08 *K*42(*A*) —), after purification by the aforementioned procedure, still contained 3–5 per cent protein, which could be removed by incubation with papain or by treatment with 45 per cent phenol at 65° C for 15 min. Neither method alters the chemical composition of the acidic capsular polysaccharide, which contains galactose (37 per cent,) fucose (18 per cent), galacturonic acid (33 per cent), glucosamine (2·5 per cent), and in addition the following radicals: *O*-acetyl (6·4 per cent), *N*-acetyl (0·6 per cent) and *N*-acyl (0·8 per cent, calculated as β-hydroxy-myristic acid). Hydrolysis with N sulphuric acid at 100° C for 2 h gave rise to an aldobiuronic acid, $[\alpha]^{25}_{5461} = +\ 53{\cdot}3°$, consisting of galacturonic acid and fucose as the reducing end. The disaccharide was obtained by preparative paper chromatography in a yield of 26 per cent. The lipopolysaccharide of *E. coli A*295*b*(08 : *K*42(*A*) —) was found to be composed of glucosamine, heptose, galactose, glucose and mannose (chemotype III (see ref. 1)) with additional acetyl groups and long-chain fatty acids. Thus, the acidic polysaccharide can be chemically differentiated from the lipopolysaccharide of the same strain by its content of fucose and galacturonic acid; its purity with respect to possibly contaminating lipopolysaccharide can be judged by testing for the absence of heptose, glucose and/or mannose.

Serological tests were carried out in order to elucidate the relationship of these acidic polysaccharides to known *E. coli* antigens. In gel-diffusion tests, saline extracts of living organisms of the two closely related strains *RVC*2907 (0141 : *K*85*ab* → *ac* : *H*4) and *D*295(0141 *K*85*ac* . *H*4) were tested against homologous (and heterologous) antisera. In addition to common precipitation lines, each strain showed a characteristic band as an expression of the differences in specificity found also by agglutination techniques, that is, differences of the K antigens. These bands were identical with those obtained by precipitation of the purified acidic polysaccharides and the corresponding bacterial antisera. By exhaustive precipitation (absorption) using the acidic polysaccharide, it was possible to remove from an OK serum the precipitins responsible for the strain-specific K antigen line and all homologous K agglutinins. It should also be mentioned that in gel diffusion tests the lipopolysaccharides (O antigens) of these two strains are identical and unrelated to the K antigen bands. With and without Freund's adjuvant, the purified acidic polysaccharide of *RVC*2907 is non-antigenic in rabbits

In serological tests with the acidic polysaccharide from *E coli A*285*b*(08 . *K*42(*A*) —) we found that this substance will remove from a homologous OK serum almost all agglutinins for the living organisms, whereas O antibodies were not absorbed In gel-diffusion tests with bacterial extracts (saline) the absorbed serum did not give any precipitation line characteristic for the K antigen Clear-cut results were also obtained using the passive hæmagglutination technique[12,13] For this purpose the following sera were used an OK serum against 08 *K*42, a pure *K*42 serum produced by absorption of the OK serum with *E coli D*284(08 . *K*-), a K^--form of the strain 08 *K*42, and a pure O serum Human blood group B erythrocytes were sensitized with the lipopolysaccharide (O antigen) or with the acidic polysaccharide respectively It was found that the acidic polysaccharide modified erythrocytes directly, that is, without alkali or heat pre-treatment[13] In the hæmagglutinating systems the acidic polysaccharide was found to be highly reactive with OK and K sera (titres of 1 20480 in both systems), but not reactive at all with O serum (titre 1 10) On the other hand, the lipopolysaccharide was highly reactive with OK and O sera, but not reactive at all with K serum

Prof Michael Heidelberger, Institute of Microbiology, New Brunswick, New Jersey, kindly tested the two acidic capsular polysaccharides, described here, for cross-precipitation with *Pneumococcus* horse antisera He found the acidic polysaccharide of *E coli* 0141 *K*85(*ab*→*ac*) to cross-react strongly with type V antiserum and less markedly with type II antiserum The acidic polysaccharide from *E coli* 08 *K*42 showed cross-reactivity with type XXV antiserum These cross-reactions, which are based on common structures probably including identical uronic acid units, may be of value for the elaboration of specific structures in the respective acid polysaccharides

Since there are several similarities between *E coli* strains with K antigens of the A type and capsulated *Klebsiella* strains, it might be mentioned here that recently Barker *et al*[14] have described an acidic polysaccharide from a *Klebsiella* strain which is mainly composed of glucose, fucose and glucuronic acid

The acidic polysaccharides with serological K specificity are distinct from another type of acidic polysaccharides, which appear to be similar to or identical with those described by Goebel (colanic acid[15]), Anderson[16] and Wilkinson[17] and which are probably the *M* antigens common to many Enterobacteriaceae These rather ubiquitous acidic slime substances were separated from the acidic polysaccharides with K specificity by fractional 'Cetavlon' precipitation Separation is effected as follows the aqueous phase of phenol/water extracts (65° C (ref 6)) is dialysed, concentrated and ultracentrifuged at 105,000*g* (sedimentation of the lipopolysaccharide) and the supernatant is lyophilized The resulting material is dissolved in 0 25 molar sodium chloride and 'Cetavlon' is added to precipitate the nucleic acid fraction, which is removed by centrifugation The supernatant is stirred and slowly diluted with water The acidic slime substance precipitates as 'Cetavlon' salt after the addition of 0 5–1 volume of water, whereas the acidic capsular polysaccharide with K specificity is precipitated only after the addition of 1 5–2 volumes of water The precipitates are removed by centrifugation as they appear As an example from the mucoid phase of *E coli* 059 *K*(?) *H*19, grown at 18° C, the following polysaccharides could be extracted and separated 2 5 per cent lipopolysaccharide (O antigen), composed of glucosamine, heptose glucose and mannose (and traces of galactose), 9 per cent acidic slime substance (*M*), composed of glucuronic acid, galactose, glucose and fucose, 2 7 per cent acidic polysaccharide (*K*)—composed of galacturonic acid, glucosamine, galactose and mannose From the same strain, grown at 37° C, only lipopolysaccharide (3 2 per cent) and acidic polysaccharide (4 8 per cent) were isolated, but no acidic slime substance It is remarkable that a single bacterial species is able to synthesize these different complex polysaccharides

More detailed accounts of our work on acidic polysaccharides isolated from capsular antigens of *Escherichia* strains will be published later

We thank Prof O Westphal for his advice and criticism and for his continuous interest in this work We also thank Prof M Heidelberger for carrying out cross-precipitation tests of the acidic *E coli* capsular polysaccharides with *Pneumococcus* horse antisera

REVERSAL OF PHOTOPERIODIC INDUCTION OF STRAWBERRIES WITH MALEIC HYDRAZIDE

By P A THOMPSON

Scottish Horticultural Research Institute, Mylnefield, Invergowrie, Dundee

IT has been shown[1] that treatment with maleic hydrazide, at levels which do not reduce the rate of leaf production, can prevent flower truss initiation in strawberry plants growing in inductive short-day cycles This substance has also been found[2] to inhibit flower initiation in Biloxi soybean, chrysanthemum and peppermint, but it was not certain that the effect was directly on the processes of flower initiation rather than a general inhibition of plant growth

Experiments involving the application of maleic hydrazide to strawberry plants over the past few years have occasionally resulted in the time of treatment being coincident with, or immediately successive to, the time of flower initiation, and this has resulted in a reversion of the flower shoot to a more or less vegetative condition in several strawberry varieties

In the first experiment a range of concentrations of maleic hydrazide was applied as a single dose to the leaves of plants of the variety Talisman growing in a growth cabinet at 15° C in a photoperiod of fourteen hours Three weeks after the treatment, the plants were transferred to a warm glasshouse where they were grown

Table 1. EFFECT OF A RANGE OF CONCENTRATIONS OF MALEIC HYDRAZIDE (MH) ON THE INCIDENCE OF PHYLLODY IN THE STRAWBERRY VARIETY TALISMAN

Concn. of MH (μg/plant)	No. of flower trusses (per 12 plants)	Phyllody (per cent)	Mean No. leaves to flower
0	10	0	5·4
100	7	0	5·4
500	6	0	5·8
1,000	5	20	5·7
1,500	7	43	5·2
2,000	6	50	5·1
2,500	8	75	5·1
3,000	7	71	6·1

from May 2 until harvested on June 10. Table 1 shows the range of concentrations applied, the numbers of flower trusses found, the percentage of flower trusses exhibiting phyllody, and the mean number of leaves emerging between the time of treatment and the emergence of the flower truss.

Table 1 shows that the incidence of phyllody in the flowers increased with increasing concentrations of maleic hydrazide, and the appearance of a fairly extreme example of flower truss reversion is shown in Fig. 1. In this experiment the mean number of leaves between treatment and flower emergence was about 5·5, and as this variety normally has between five and six leaf primordia within its bud, it may be inferred that the treatment was applied within one plastochron of the time of flower truss initiation.

In a second experiment maleic hydrazide was applied to plants of the variety Climax by spraying whole plants with solutions containing either 125 or 62·5 p.p.m. of active ingredient twice a week for a period of six weeks—July 29–September 19. There were twenty plants in each treatment. This variety initiates flowers freely over a long period and from the beginning of the course of treatment flowers at all stages of development were present in the bud; a number of abnormal flower forms resulted. These were broadly of two types; flowers in which varying degrees of inhibition of the development of the female parts occurred, which have been described in a previous paper[3]; and inflorescences showing phyllodious development of the flowers. The former type was found on inflorescences which were two or more plastochrons old at the first treatment; the latter was confined to those inflorescences which were initiated within one plastochron before or after the start of treatment. The degree of phyllody ranged from an almost complete reversion of the whole truss similar to the condition illustrated in Fig. 1 to minor effects on individual parts of the flower, particularly the carpels, similar to that shown in Fig. 3.

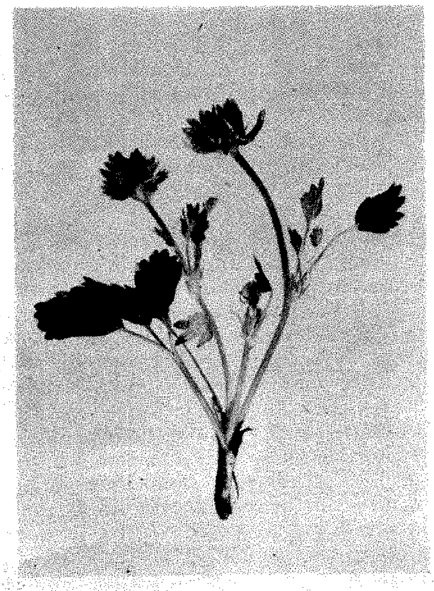

Fig. 1. Inflorescence of strawberry plant showing phyllody of the floral parts after treatment with maleic hydrazide

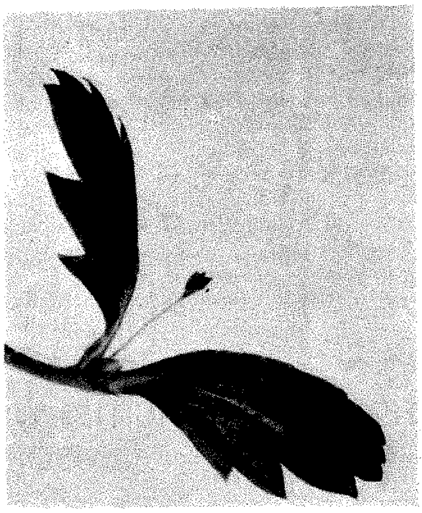

Fig. 2. Reversion of a primary flower of *Fragaria elatior* to a vegetative bud after treatment with maleic hydrazide

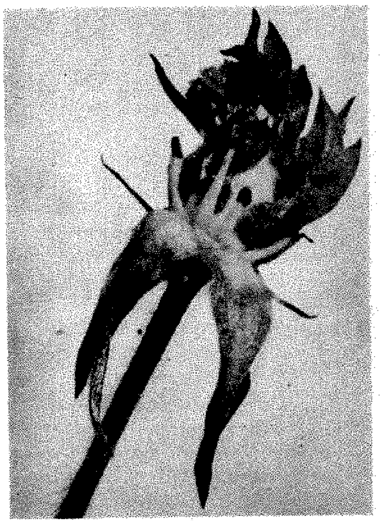

Fig. 3. Development of leafy bracts on the receptacle after treatment with maleic hydrazide

In the third experiment an aqueous solution of maleic hydrazide containing 75 p.p.m. of active constituent was sprayed twice weekly for four weeks—October 12–November 9—on to plants of the species *Fragaria elatior* (Ehr.) growing in a warm glasshouse; three plants out of the eight so treated produced flowers showing varying degrees of phyllody in positions which indicated that the flowers had just been initiated at the time of the first treatment. In one instance, illustrated in Fig. 2, the primary flower had reverted to a vegetative shoot bearing two bract-like leaves and a small bud in place of the flower, and other examples were found in which phyllody was confined to the development of leafy bracts on the receptacles in place of the carpels, illustrated in Fig. 3.

The results of these experiments show that not only can maleic hydrazide prevent the initiation of inflorescences in strawberries in response to favourable photoperiods, but also that it can cause a reversal of the processes following induction which normally lead to the development of a flower truss irrespective of the day-length.

The results also show that the timing of the spray was extremely critical, so that the effect was produced only if the treatment was applied within one plastochron of flower initiation. This is scarcely surprising, as the rate of development of strawberry flowers after initiation is rapid and the period during which they are subject to changes in their developmental processes is therefore short. It is not possible to indicate the nature of the changes which this treatment produced, since both the action of maleic hydrazide and the changes in the apical meristem accompanying the transition from the vegetative to the flowering condition are obscure. One may, however, conjecture that the changes which occur in the meristems are mediated through the RNA system and are produced or accompanied by alterations in the composition of this material.

In this connexion a recent paper by Butenko and Baskakov[4] is of particular interest, in which they demonstrated that maleic hydrazide-induced inhibition of callus tissue cultures could be overcome by the addition of uracil, and suggested that maleic hydrazide acts antagonistically to uracil by blocking its incorporation into the nucleic acid molecule. If the maleic hydrazide used in these experiments acted in a similar way on nucleic acid synthesis then this chemical may provide a useful tool for the investigation of the changes in the apical meristem occurring during photoperiodic induction.

DIFFERENT SPECIFICITIES OF PROLINE-ACTIVATING ENZYMES FROM SOME PLANT SPECIES

By P. J. PETERSON* and L. FOWDEN

Department of Botany, University College, London

IN recent years many amino-acid analogues have been chemically synthesized and used as antimetabolites to natural compounds in the synthesis of proteins[1], while a large number of naturally occurring, newly characterized amino- and imino-acids[2,3] appear to have been neglected in such investigations[4], although often possessing structures closely akin to the protein amino-acids. Azetidine-2-carboxylic acid, a member of the latter group of compounds and the lower homologue of proline[5,6], has a restricted distribution in some members of the Liliaceae and the closely related Agavaceae[7]. It may occur in all parts of the plant as seen in *Convallaria majalis* and *Polygonatum multiflorum*[7,8], or its distribution may be restricted to certain plant organs, especially seeds[7]. The imino-acid, which is present in the aqueous ethanol-soluble nitrogenous fraction of these plants, is not known to occur naturally in plant proteins[9] and therefore has been loosely described as a non-protein imino-acid.

When azetidine-2-carboxylic acid was supplied to germinating seeds of different species in which it does not normally occur, for example, *Phaseolus aureus*, it produced marked growth inhibition and was lethal at high concentration[4]. The degree of inhibition was dependent on the concentration supplied and on the species investigated. The severity of growth inhibition produced by azetidine-2-carboxylic acid was greater than when the same concentrations of *p*-fluorophenylalanine were supplied to seedlings. Azetidine-2-carboxylic acid also inhibited the growth of carrot tissue cultures[10], *Escherichia coli*[11] and chick embryo[4]. This behaviour has been attributed to its action as a proline analogue, where a stoichiometric replacement of proline occurred with production of abnormal proteins having impaired biological activity[4,11]. The inhibitory action of azetidine-2-carboxylic acid was reversed by addition of proline, and therefore differences in endogenous proline concentrations could explain the differing degrees of growth inhibition observed with various plant species.

The absence of incorporation of azetidine-2-carboxylic acid into the proteins of liliaceous species producing this imino-acid (where the concentration may be as high as 50 times the lethal dose for *Phaseolus aureus*[8]) and its profound growth-inhibitory action on species not normally containing it suggest that some difference must exist in specific selection mechanisms for amino-acids in these two groups of plants. A differentiation between proline and azetidine-2-carboxylic acid could result from either of two causes[4]. The Liliaceae may have evolved a sub-cellular organization that excludes azetidine-2-carboxylic acid from the sites of protein synthesis, for example, vacuolar storage, or a more subtle enzymatic selection between proline and azetidine-2-carboxylic acid may occur at one (or more) points during the elaboration of protein molecules. The second, more interesting possibility has received our attention here.

The mechanism of protein biosynthesis is well established, the initial step being the enzymatic activation of amino-acids[12]. Investigations on more or less highly purified activating enzymes have shown that each amino-acid is activated by a specific enzyme and that these enzymes exhibit high specificity, often being able to discriminate between analogues and their normal amino-acid substrates[13]. In the majority of cases, if an analogue is activated, usually measured by the adenosine-5′-triphosphate-[^{32}P]pyrophosphate (ATP-[^{32}P]PP) exchange reaction, then it is incorporated into protein. However, discrimination at a subsequent intermediate reaction in protein synthesis has been reported[14], as has discrimination at the transfer step to *S*-RNA (transfer-ribonucleic acid)[15]. A selection at a later stage appears unlikely because a 'wrong' amino-acid becomes incorporated into protein if it is produced by chemical modification of the 'correct' amino-acid while the latter is attached to its specific *S*-RNA[16,17].

The varying abilities of the proline activating enzyme from several plant sources to differentiate between its normal substrate and azetidine-2-carboxylate, used as an analogue, are reported here. The results leave little doubt that the observed selective incorporation of azetidine-2-carboxylic acid into plant proteins aforementioned can be attributed to the differences of specificity observed for this enzyme when obtained from different sources. However, the reason why many liliaceous plants elaborate azetidine-2-carboxylic acid at all remains an intriguing, but unsolved, problem.

Enzyme Preparation and Assay Procedure. Four plant species were used in this investigation. Two did not contain azetidine-2-carboxylic acid, namely *Pisum sativum* L. var. Carter's little marvel (garden pea) and *Phaseolus aureus* (mung bean), while the other two, *Convallaria majalis* (lily-of-the-valley) and *Polygonatum multiflorum* (a Solomon's seal), contained azetidine-2-carboxylic acid in high concentration. The first two species were used for convenience as seeds, and ground to flour before use, while the latter species were collected as rhizomes in mid-March and stored at 1° C. The apical 3-cm long portion of the rhizomes was used for enzyme preparation. All manipulations were carried out in a cold room at 1° C.

Seed flour (45 g) was ground by pestle and mortar with washed sand (5 g) in a solution (135 ml.) of 0·1 M *tris* buffer (2-amino-2-hydroxymethylpropane-1,3-diol-HCl,

---

* Holder of a New Zealand National Research Fellowship.

*p*H 7 5) containing 0 4 M sucrose. Rhizome tissue (60 g) was homogenized (0 5 min) at 12,000 r p.m with the same *tris* buffer-sucrose solution (150 ml) The slurries were pressed through cheesecloth and the liquid collected and centrifuged at 20,000*g* for 15 min (step *A*) The cell-free supernatant was diluted with water (45 ml) and then protein was precipitated by adding 0 1 M acetic acid to *p*H 4 2 and sedimented at 12,000*g* for 5 min The protein was re-suspended in *tris* buffer (95 ml) without sucrose, centrifuged to remove insoluble denatured material and fractionated over known *p*H ranges with centrifuging as before The precipitated protein was dissolved finally in 0 1 M *tris* buffer *p*H 7 9, 10 ml (step *B*) Further enzyme purification was achieved by ammonium sulphate precipitation of these fractions following standard procedure with additions of solid salt to give known saturations, precipitated protein was sedimented as before The precipitates were dissolved in *tris* buffer as above for the acid fractions and the solutions were dialysed for not less than 2 h against the same *tris* buffer (step *C*)

[^{32}P] Pyrophosphate was prepared from sodium [^{32}P] orthophosphate, by raising the *p*H to about 9, adding carrier Na_2HPO_4 and pyrolysing in a platinum crucible (500° C, 5 h)[18] Paper chromatography on 1 per cent (w/v) oxalic acid-washed Whatman No 2 paper with two solvent systems[19,20], followed by radioactivity scanning, showed the purity to be greater than 98 per cent pyrophosphate

The enzyme assay conditions are described in the footnote to Table 1 Reactions were stopped by cooling and adding cold 7 5 per cent (w/v) trichloroacetic acid (2 ml) Precipitated protein was sedimented (1,500*g*) and supernatant samples (1 ml) were added to 0 1 M sodium acetate (2 6 ml) ATP-[^{32}P]PP exchange was measured by a charcoal adsorption method[21,22] using acid-washed[23] 'Darco *G* 60' charcoal The two terminal phosphate groups of the charcoal-adsorbed ATP were hydrolysed (100° C, 15 min) with N hydrochloric acid (4 ml) and the radioactivity determined in 1 ml samples Inorganic phosphate determinations were also carried out on the hydrolysate[24] Protein content of the enzyme preparations was determined using bovine plasma albumin as standard[25] The results are expressed in terms of per cent exchange and rate of exchange[26] Each set of results presented was obtained from a different enzyme preparation

Results of Activation Investigations The soluble fractions obtained from different plant tissues after step *A* were tested for their ability to catalyse the ATP-[^{32}P]PP exchange The results shown in Table 1 (only two species are included to avoid repetition) indicate that added proline did not stimulate the exchange, although the addition of a 'complete mixture', that is, twenty protein amino-acids, did cause some stimulation of exchange Hence, in order to investigate proline activation a marked lowering of the endogenous exchange rate was essential

Table 1 EFFECT OF POTASSIUM FLUORIDE ON THE ACTIVATION OF AMINO-ACIDS BY HOMOGENATES OF *Pisum sativum* AND *Phaseolus aureus*, MEASURED BY ATP-[^{32}P]PP EXCHANGE

Species	Fluoride (μmole)	Amino-acid	Per cent exchange	*R* (μmole exchanged/h/mg protein)	*ΔR*

For incubation system, refer to legend Table 1 The fractionation *p*H ranges recorded were established on solutions which were first precipitated to *p*H 4 2 redissolved in 0 1 M *tris*-HCl buffer *p*H 7 6

*L-azetidine-2-carboxylic acid

An extract containing protein obtained from the original homogenate after precipitation at *p*H 5, that is, a '*p*H 5 fraction', showed some proline activating activity but the endogenous rate was still very high. Better results were obtained after step *B*, in which the protein was precipitated first down to *p*H 4 2, then redissolved to give an extract that was fractionally precipitated at several known *p*H values

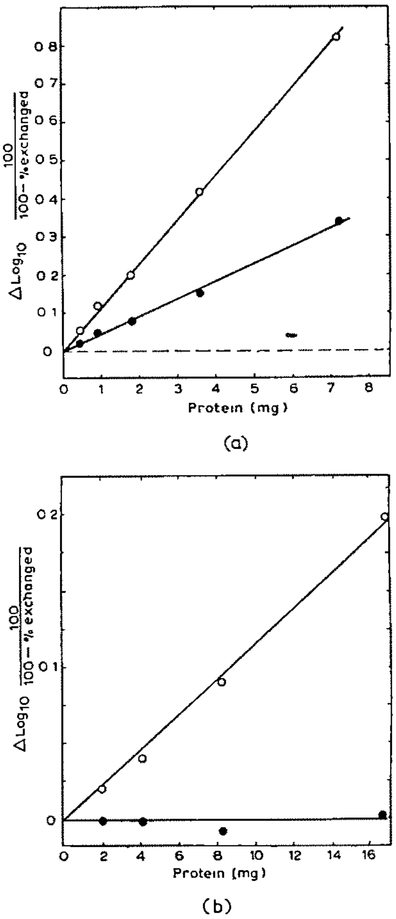

Fig 1 Effect of concentration of enzyme from protein fractions of (*a*) *Phaseolus aureus* and (*b*) *Polygonatum multiflorum* on L-proline (○) and L-azetidine-2-carboxylic acid (●) stimulated rates of ATP-[^{32}P]PP exchange Assayed under standard conditions described in Table 1

ATP-ase activity was present in the whole homogenate (step *A*) Potassium fluoride was added to inhibit this activity but also suppressed activation, especially in the pea seed extract, and was therefore omitted after subsequent purification steps where the ATP-ase was negligible This effect of fluoride on activation has been noted previously by other workers on higher plant extracts[27], but is absent in investigations on micro-organisms[22]

Table 2 shows the proline and azetidine-2-carboxylic acid activation values obtained for the four species together with results for the 'complete mixture' Data are given only for those *p*H values that correspond to the highest proline activation Protein precipitated over *p*H ranges above those shown exhibited markedly less activity, while measurements with protein precipitated below *p*H 4 2 were difficult owing to instability of the enzyme in these acid solutions The *p*H range over which the most active fraction precipitated was dependent on the origin and the purity of the protein and, in view of the differences in protein composition between dicotyledonous and monocotyledonous seeds, it is not surprising that species differences were encountered as is shown in Table 2

The most significant result seen in Table 2 is that azetidine-2-carboxylic acid is activated at about one-third of the rate of proline in pea and mung bean (species which do not normally contain azetidine-2-carboxylic acid), yet in the two liliaceous species, azetidine-2-carboxylic acid, which is normally present, is not activated The same relative activation values as those presented in Table 2 were obtained for the four species at all the other *p*H-precipitation ranges tested The possibility that the differences in the ability to activate azetidine-2-carboxylic acid were not a function of species but merely of the tissue chosen for enzyme preparation, that is, seed compared with rhizome, was eliminated by showing that similar preparations from seed of *Convallaria majalis* also failed to activate the analogue

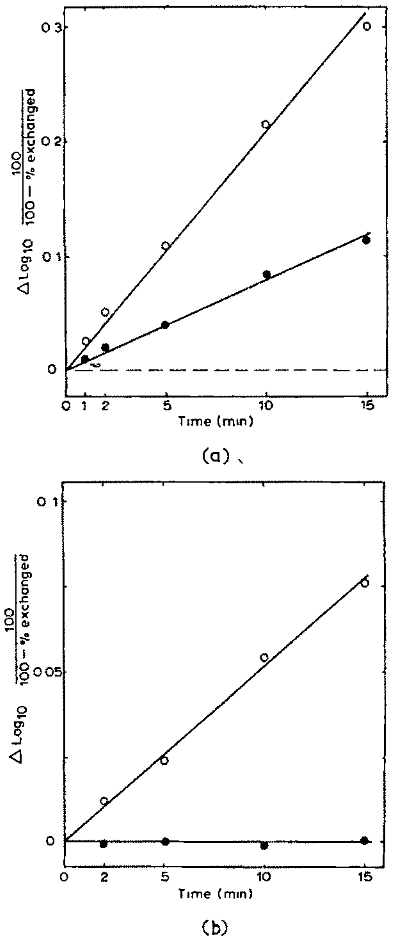

Fig 2 Effect of time of incubation of enzyme preparations from (*a*) *Phaseolus aureus* and (*b*) *Polygonatum multiflorum* on L-proline (○) and L-azetidine-2-carboxylic acid (●) stimulated rates of ATP-[^{32}P]PP exchange Assayed under standard conditions described in Table 1

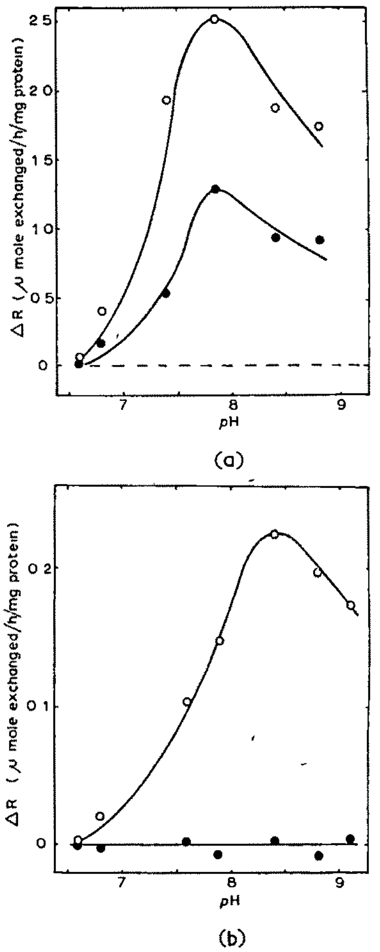

Fig 3 Variation of rate of L-proline (○) and L-azetidine-2-carboxylic acid (●) stimulated ATP-[^{32}P]PP exchange with *p*H, for enzyme preparations from (*a*) *Phaseolus aureus* and (*b*) *Polygonatum multiflorum* 0 1 M Citrate-NaOH buffer *p*H 6 6, or 0 1 M *tris*-HCl buffers *p*H 6 8–9 1 were used to dissolve final precipitated protein Assayed under standard conditions described in Table 1 except for the *p*H values of buffer used

A series of further experiments were performed to determine the relationships existing between the rates of activation of azetidine-2-carboxylic acid and proline and enzyme concentration (Fig 1), reaction time (Fig 2), and *p*H (Fig 3)

Throughout the fractionation procedure of mung bean or pea extracts, an observed ability to activate proline was always accompanied by a proportionately smaller activation of azetidine-2-carboxylic acid, indicating that only one enzyme was involved This conclusion was confirmed by adding both imino-acids together (5 μmole of each) when the rate of activation remained the same as when proline alone was added (Table 3) The same result was obtained when the imino-acids were added at 2 5 or 10 μmole concentration Had two enzymes been involved, the rate would have been close to the sum of the rates determined for the two imino-acids separately

The *p*H-precipitated protein fractions from mung bean and Solomon's seal rhizome extracts contained enzymes

Table 3 EFFECT OF ADDITION OF L-PROLINE AND,-OR, L-AZETIDINE-2-CARBOXYLIC ACID, ON THE RATE OF ATP-[^{32}P]PP EXCHANGE IN *p*H 4 2–4 6 ACETIC ACID PRECIPITATED PROTEIN FRACTION FROM *Phaseolus aureus*

L-A 2 C*	18 75	0 834	0 732

* L-Azetidine-2-carboxylic acid

capable of activating twelve and eleven other protein amino-acids respectively A protein fraction further purified by precipitation between 60 and 70 per cent saturation ammonium sulphate contained the highest proportion of the proline activating activity and also had the highest enzymatic specific activity This fraction also activated fewer amino-acids and their relative per cent activations compared with the value for proline were lower The ratios of proline to azetidine-2-carboxylic acid activation rates were the same for all the fractions precipitated from mung bean extracts by different concentrations of ammonium sulphate, none of the ammonium sulphate precipitates from Solomon's seal extracts showed any capacity to activate azetidine-2-carboxylic acid

Higher plants have rarely been used as experimental material for investigations of amino-acid activation and they have served even less often as starting material for enzyme purification Previously, only weak proline activating activity has been encountered in higher plant extracts, but we have found the mung bean especially to be excellent material for purification of this enzymatic activity and as a source of a number of other activating enzymes

Species differences observed in the properties of amino-acid activating enzymes do not appear to have been reported previously However, the following article describes a similar difference in the specificity of the methionine activating enzyme present in wild-type and in an ethionine-resistant mutant of *Coprinus* Presumably one may infer that species producing azetidine-2-carboxylate have evolved a proline activating enzyme differing slightly in protein conformational features (tertiary structure) from the enzyme present in other species, and possessing a subtly modified active centre that can reject azetidine-2-carboxylic acid The proposed structural modification may conceivably be attributed to the presence of different amino-acid sequences in the region of the active centres of the same enzyme from different plant species Structural variability of this type already has been established for certain proteins obtained from different animal species[28]

Further purification of the proline activating enzyme and the testing of other naturally occurring proline analogues and imino-acids have been carried out and will be reported shortly

We thank the New Zealand Council of Scientific and Industrial Research for a fellowship for one of us (P J P) and the Central Research Fund of the University of London for an apparatus grant.

STRUCTURAL GENE FOR THE METHIONINE-ACTIVATING ENZYME AND ITS MUTATION AS A CAUSE OF RESISTANCE TO ETHIONINE

By Prof D. LEWIS, F R S

Department of Botany, University College, London

ON the present genetical theory of the synthesis of enzymes there should be, in all organisms, at least twenty genes for the postulated twenty enzymes which activate the twenty proper amino-acids in proteins Some of these enzymes, if they are hetero-polymers, would require two structural genes as in hæmoglobin None of these genes has been found in any organism The common method of obtaining biochemical mutants in micro-organisms by growing the cultures on supplemented media will only detect mutants of genes concerned with the synthesis of relatively simple molecules which can be supplied in the medium An enzyme which is primarily essential for protein synthesis would be irreplaceable under all conditions It is not surprising, therefore, that genes for the activating enzymes have not been detected A specific search for the gene of the histidine-activating enzyme in *Salmonella* has been made by Ames and Hartman[1] They tested for the histidine-activating enzyme in cultures with single-site and multi-site mutations in the cluster of the histidine biosynthetic genes No differences were found in the activating enzymes in these mutant stocks It is doubtful if this method, even if extended to the whole genome, would yield results, because most of these unselected mutations and deletions would cause complete inactivity or loss of the enzyme, and this would be lethal

The method I have used to detect the gene for the methionine-activating enzyme is to screen for small non-lethal changes in the active sites of the enzyme by using analogues of methionine

Analogues of five amino-acids, when applied to higher or micro-organisms, are known to become incorporated into protein, for reviews see refs 2 and 3 Some of these, such as azetidine-2-carboxylic acid, are highly toxic to many organisms[4,5] At the other extreme is selenomethionine, which not only replaces all the methionine in the protein of *Escherichia coli* without effect on growth but also can support linear growth in the complete absence of a source of sulphur[6]

Ethionine, the analogue of methionine, used in my experiments, is known to be incorporated into the protein of rat tissue[7], *Tetrahymena*[8], yeast[9,10] and *Bacillus subtilis*[10,11] It is toxic to yeast but not to *Bacillus subtilis* The toxicity of ethionine has been attributed to (1) its effect on the properties of proteins by incorporation, (2) by interfering with lipotrophic activity, and (3) by interfering with transmethylation[10]

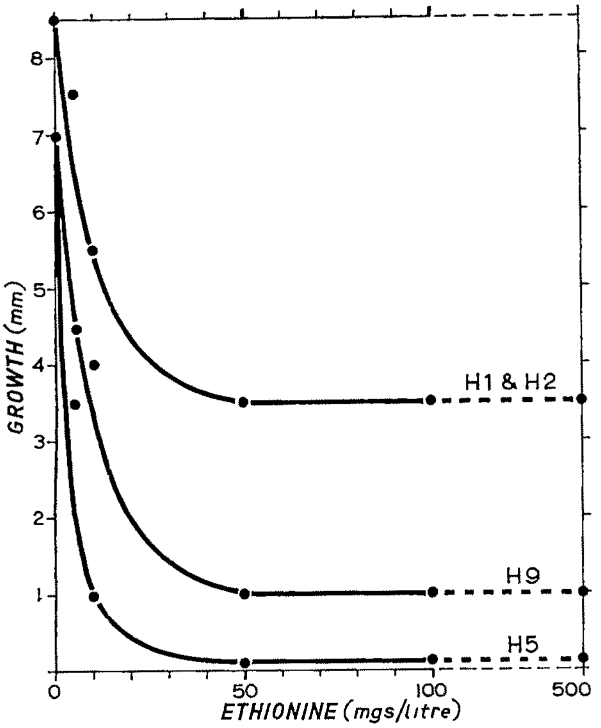

Fig 1 Radial growth of wild-type stocks on solid medium in 24 h, 100 mg/l = 0·61 × 10^{-3} M ethionine

Effect of Ethionine on Growth of Coprinus lagopus. The organism used in these investigations is the basidiomycete fungus, *Coprinus lagopus* (*sensu* Buller). Descriptions of its genetic system and method of culture are given by Lewis[12]. Methionine was the amino-acid chosen for investigation because seven structural genes for methionine synthesis and a system of suppressor genes have been mapped and investigated. The effects of different concentrations of ethionine are given in Fig 1, where it can be seen that all the wild-type stocks tested are inhibited by ethionine but to different degrees. The analogue norleucine, on the other hand, has no effect on growth even at saturation.

The inhibiting effect of ethionine was partially, but not completely, removed by methionine (Fig 2). A methionine-requiring mutant, *me*-1, reacts differently to the mixture, the methionine being much more effective on the *me*-1 mutant in removing the inhibitory effect of the analogue. This differential reaction to the mixture is under the control of a single gene, but the full significance of the differences is not known and will not be discussed in relation to the main subject of this report.

Mutation to Resistance to Ethionine. Mutations conferring resistance to ethionine were selected by sowing uninucleate oidia on solid minimal medium with the addition of 0·61 × 10^{-3} M L-ethionine. Four plates, with 3 × 10^{6} oidia each, were sown of *H*5 oidia. At this density of sowing there was an uncountable number of small irregular colonies with submerged hyphæ. Twenty of the largest of these colonies were isolated, but none were found to be resistant mutants. During the course of other experiments, where total oidial numbers were not known, two genuine resistant mutants have been obtained from untreated oidia. Treatment with ultra-violet light, which gave a kill of 84 per cent, produced three good resistant colonies from 2 plates sown with 5·4 × 10^{5} oidia per plate. One of these mutants, *H*5 *E*2, has been used extensively in these experiments; its growth on ethionine medium is given in Fig 3.

From the analysis of appropriate crosses the mutant *E* 2 was found to differ from its wild-type progenitor in a single gene which is recessive to the wild allele when tested in a dikaryon. This gene is linked to two methionine synthesizing genes, *me*-2 and *me*-6.

Mutants resistant to ethionine have also been selected from a stock *PR*2301 which requires methionine due to a mutation of the gene *me*-1 controlling the synthetic step between cystathionine and homocysteine[12]. When oidia of this stock are sown on minimal medium, 1 in 10^{5} grow as a result of recessive mutation of a suppressor gene[12]. If the oidia of the same *me*-1 stock are sown on minimal media with 0·61 × 10^{-3} M L-ethionine, 3 in 10^{7} oidia grow into colonies and have the double property of being both able to grow without methionine and are resistant to ethionine. These mutants are recessive. The growth on ethionine of one of these mutants, *Ms*13, is given in Fig 3. The significance of this double property of the mutant is the subject of another investigation, but this mutant is included here because, as will be described, it is of importance in the interpretation of the biochemical cause of the resistance to ethionine.

Incorporation of Ethionine into Protein. The resistance to ethionine in the mutants could be caused by a blockage in one or more steps in the entry into the cell or in its metabolism. It could be prevented from entry by the lack of or change in a permease system. It could enter and then be immediately metabolized to a harmless compound, or it may be accumulated in the cell and be prevented from being incorporated into the protein by a change in the specific activating enzyme or by a change in the specific transfer ribonucleic acid. Furthermore, it may be prevented from supplying ethyl groups to precursors of important methylated compounds.

To investigate the metabolic fate of ethionine, 0·14 × 10^{-3} M ^{35}S DL-ethionine, 13·7 mc./mM, obtained from the Radiochemical Centre, Amersham, was added to liquid minimal medium. This concentration of ethionine allowed enough growth in liquid medium of both sensitive and resistant strains for the analysis. Unshaken culture flasks inoculated with *H*5, *E*2 and *Ms*13 cultures were collected after 5 days' growth. The mycelium was macerated in sodium borate buffer *p*H 8·0 and the protein was precipi-

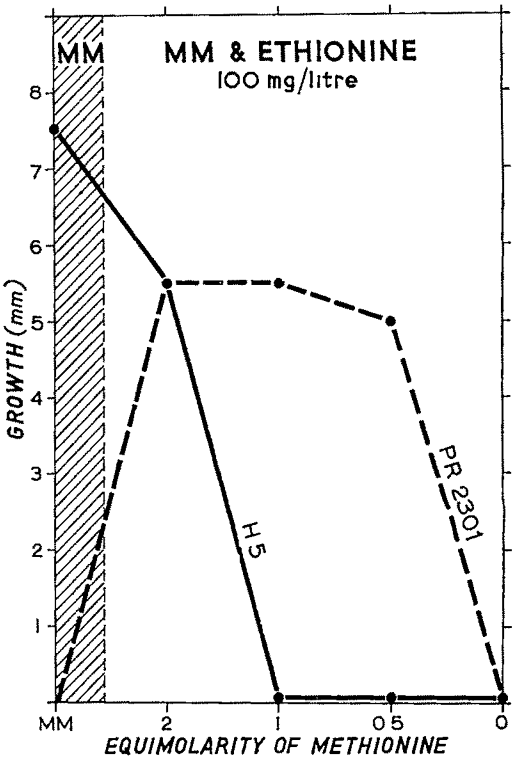

Fig 2 Radial growth of wild-type *H*5 and a methionine-requiring mutant *PR*2301 on minimal medium (*MM*) and on ethionine with and without methionine

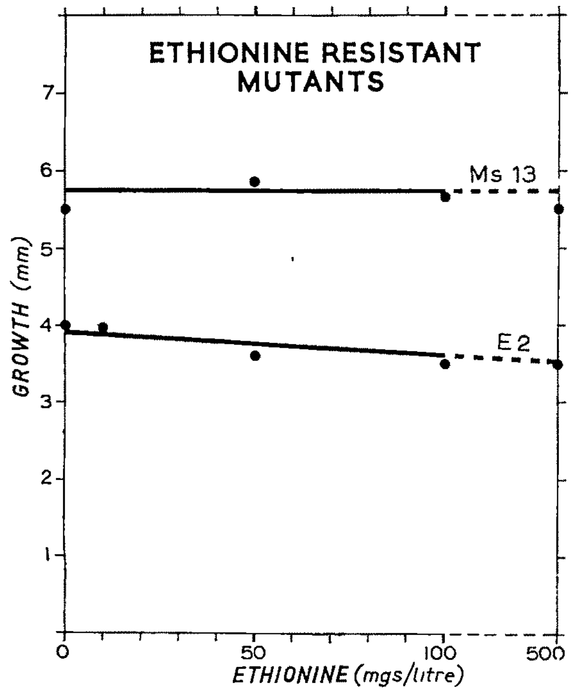

Fig. 3. Radial growth of resistant mutants on solid medium in 24 h

tated in 5 per cent trichloracetic acid. The washed TCA-insoluble fraction containing the protein was hydrolysed in hydrochloric acid. The amino-acids of both the TCA-soluble and insoluble fractions were separated by chromatography in a butanol–acetic acid–water mixture. The summary of the results is given in Tables 1 and 2.

From Table 1 it is clear that in all three cultures ethionine entered the cells and that radioactive sulphur amino-acids were present in the protein. The resistant mutants have less sulphur-35 compounds in both the free soluble pool and in the protein than the wild-type and mutant *E*2 has a lower amount than *Ms*13. From Table 2 it is apparent that ethionine is found in the TCA-soluble fraction of *H*5 and *E*2 but not in *Ms*13. The very large amount of the unidentified, ninhydrin positive spot *X* is characteristic of the soluble fraction but is absent from the protein. The results showed that in the protein of the mutant *E*2 ethionine is absent. Statistically it is not possible to exclude up to 3 per cent of the ethionine-level of the wild-type *H*5 or at about 0·3 per cent of the total activity of sulphur-35. In the wild *H*5 stock ethionine is 9 per cent and in the mutant *Ms*13 it is 17 per cent of the total activity of sulphur-35. The results with *E*2 in which ethionine is not incorporated would suggest that the inhibitory effect of ethionine is due to incorporation. Clearly from the fact that the resistant mutant *Ms*13 incorporates ethionine into its protein we must conclude, however, that the primary inhibitory effect of ethionine is not due to incorporation into protein.

Table 1. INCORPORATION OF ^{35}S FROM ^{35}S-ETHIONINE INTO THE TCA-SOLUBLE (POOL) FRACTION, PROTEIN FRACTION AND ACID HYDROLYSATE OF THE PROTEIN FRACTION

Culture	Counts/400 sec/g dry weight mycelium		Counts/400 sec/mg protein after hydrolysis
	TCA soluble fraction	Protein fraction*	Protein hydrolysate
Wild *H*5	20,291	25,261	10,503
Resistant *E*2	14,642	7,902	4,002
Resistant *Ms*13	21,690	13,810	7,109

* By difference between radioactivity in homogenate and TCA-soluble fraction.

Table 2. INCORPORATION OF ^{35}S FROM ^{35}S-ETHIONINE INTO AMINO-ACIDS OF THE TCA-SOLUBLE AND PROTEIN FRACTIONS

	Radioactivity (as % of total counts in the three *S*-containing labelled spots)					
Culture	'Pool' amino-acids			Protein hydrolysate		
	Spot X	Methionine	Ethionine	Cyst(e)ine	Methionine	Ethionine
Wild *H*5	96·7	0·0	3·3	54	37	9
Resistant *E*2	93·6	0·0	6·4	65	45	0
Resistant *Ms*13	91·0	9·0	0·0	47	36	17

Methionine-activating Enzyme in Wild-type and Mutant E2. Cultures of wild-type *H*5 and resistant mutant *E*2 were grown in 1·8 litres of liquid minimal medium. To the *E*2 culture flasks 0·01 × 10^{-3} M L-ethionine per litre was added to discourage growth of back mutations to wild-type. Collection and extraction of the protein were carried out at 4° C. The washed mycelium was homogenized in sucrose *tris* buffer, *p*H 7·6. The activities of the activating enzymes were determined by the pyrophosphate, adenosinetriphosphate exchange method as followed by Peterson and Fowden[4].

The whole crude homogenate of *H*5 possessed an endogenous activity that was slightly increased equally on addition of methionine or ethionine. The mutant *E*2 was similar except that the increase in activity with ethionine was about a quarter that obtained with *H*5. The levels above the endogenous rates were so low that these results were of no value without further purification of the enzyme.

Fractionation at three different *p*H's with acetic acid did not improve the activity. But ammonium sulphate fractionation resulted in a spectacular increase in the methionine activity in the 50–100 per cent saturation fraction. The bulk of the protein was in the 0–50 per cent saturation fraction but this had little or no activity, towards methionine.

Table 3. TOTAL COUNTS IN 400 SEC ON 4 SPECIMENS OF EACH ASSAY. THE AMOUNTS OF PROTEIN IN THE *H*5 AND *E*2 TESTS ARE NOT THE SAME, BUT A VALID COMPARISON CAN BE MADE AS A PERCENTAGE OF THE ACTIVITY WITH THE COMPLETE AMINO-ACIDS (LAST COLUMN)

*H*5	Actual counts	Counts above control	% above control
Control	3,346	—	—
Ethionine	4,760	1,414	7·9
Ethionine + methionine	6,329	2,983	16·0
Methionine	6,306	2,960	16·0
Complete amino-acids	21,897	18,551	100
*E*2			
Control	4,836	—	—
Ethionine	5,064	228	0·5
Ethionine + methionine	11,993	7,157	16·8
Methionine	12,500	7,664	18·0
Complete amino-acids	47,221	42,385	100

The results of counts of radioactive ATP from the 50–100 per cent fraction, given in Table 3, show that in the wild *H*5 ethionine is activated at a level of 48 per cent of the methionine activity. In the mutant *E*2, on the other hand, ethionine is not activated or at most to about 3 per cent of the methionine-level. A chromatographic test of the purity of the L-ethionine used for the activation test showed trace impurities of cysteine and methionine, which could account entirely for the slight activation observed with the mutant. The result from the mixture of ethionine and methionine shows that only one enzyme is concerned with the activation of both methionine and its analogue.

Resistance of Choline-less Mutants. In view of the hypothesis of the inhibitory mechanism of ethionine expounded in the next section it became important to test for the resistance to ethionine of certain choline-less mutants. Two mutants chol 1 and chol 2 (ref. 13) were tested on choline medium with 50 mg/l. of L-ethionine. Growth was at about 75 per cent of that occurring on medium containing choline alone, showing that they were resistant to ethionine.

Discussion and Conclusions The ethionine-resistant mutant $E2$ differs from wild-type in that the mutant does not incorporate ethionine into protein and the methionine-activating enzyme does not activate ethionine The gene for ethionine resistance is therefore the structural gene for the methionine-activating enzyme, and is designated *meth AE* The mutational change must have changed the active sites in a way that has altered the specificity so that the mutant sites can effectively fit methionine but not ethionine Presumably a single amino-acid substitution in the active site has occurred The difference discovered by Peterson and Fowden[4] between the proline-activating enzyme of different species of plants could have a similar mutational origin of long standing

The resistant mutant, $Ms13$, incorporated ethionine into the protein at a level that was nearly twice as high as ethionine incorporation into the sensitive wild-stock The inhibitory effect of ethionine is therefore not caused by incorporation It is also not caused by ethionine being an end-product repressor of methionine synthesizing enzymes since methionine is synthesized and incorporated in the wild-type in the presence of ethionine

The hypothesis proposed is that ethionine is inhibitory in the sensitive $H5$ because it transethylates the precursors of metabolically important methylated compounds such as choline

In support of this is that cholineless mutants which are unable to synthesize choline are resistant to ethionine If this hypothesis is accepted then the mutant gene *meth AE* of $E2$ must not only be a block to the incorporation of ethionine into the protein but also a block to transethylation From this it follows that the methionine-activating enzyme mediates not only the first step in amino-acid incorporation but also the first step in transmethylation In the $Ms13$ mutant the block is not at the first step of the activating enzyme but at a later step in the transmethylation system This mutant can transfer methyl, but not ethyl, groups There would, therefore, be an accumulation of an ethylated compound, and this in turn would relieve the demand for ethionine and increase its availability for incorporation into protein Hence the double amount of ethionine in the protein of $Ms13$

Cantoni[14] has shown that S-adenosylmethionine is the active form of methionine for transmethylation, and that this is formed by a reaction requiring ATP and releasing PPi and Pi catalysed by an activating enzyme Parks[10] has shown that S-adenosylethionine is synthesized in the presence of ethionine and that transethylation occurs with an *in vitro* system There are two possibilities to explain the results of the work recorded here (1) The methionine-activating enzyme for the synthesis of methionine-AMP-enzyme complex leading to incorporation, and the activating enzyme for the synthesis of S-adenosylmethionine leading to transmethylation, are one and the same enzyme, (2) two or more enzymes are involved and the S-adenosylmethionine is synthesized sequentially from the methionine-AMP-complex

The first possibility invokes one enzyme carrying out two parallel reactions, the second postulates a complicated dephosphorylation and rearrangement of the adenosine from the terminal carboxyl group to the sulphur atom Experiments to distinguish between these possibilities are planned

The significance, if any, of the close linkage of the *meth AE* gene with the complex of two structural genes concerned in methionine synthesis is not apparent Close linkage of genes with sequential functions suggests a common repressor system by the end product (Jacob and Monod[15]) It is unlikely that the *meth AE* enzyme is repressed by methionine, for this would stop protein synthesis Possibly the control of transmethylation may be a factor to consider if repression is established

At the beginning of the experiments it was hoped that genes controlling the synthesis of specific transfer RNA would also be found in the methionine system, but if the hypothesis of transmethylation is correct there is no selective technique available for obtaining viable mutants of the transfer RNA with the methionine system

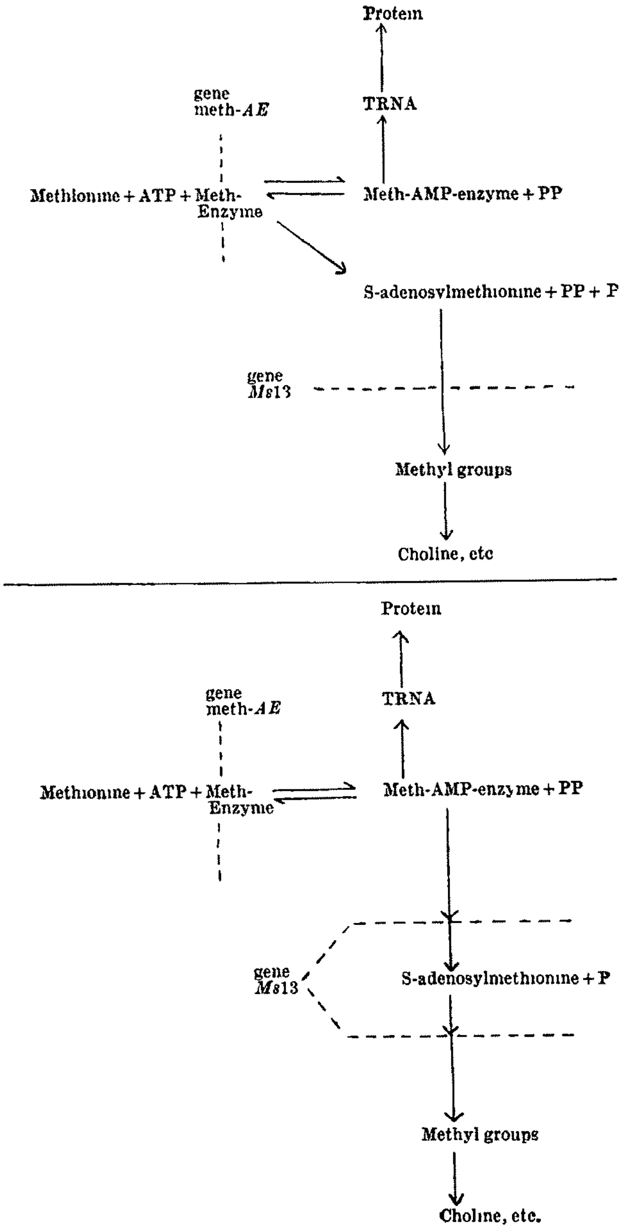

Fig 4 Alternative hypotheses to explain the action of the *meth AE* and the *Ms*13 genes

I thank Mr Peterson for help with the protein fractionation and with the ATP-pyrophosphate method, Mr D Walls for his assistance, and Mr H Tristram for constructive criticisms of the manuscript

LETTERS TO THE EDITOR

RADIOPHYSICS

Galactic Background Polarization at 610 Mc/s

AFTER the first successful attempt to measure the polarization of the galactic radio radiation at 408 Mc/s (refs 1 and 2), the observations were continued with improved receivers, resulting in a nearly complete survey of the polarization at 408 Mc/s of the part of the sky visible with the Dwingeloo radio telescope[3,4] The receivers used were all based on the correlation principle, correlating the signals of two crossed dipoles The results obtained were confirmed by observations made at Cambridge using the difference between the signals on two crossed dipoles[5,6] and by results obtained at Sydney, by rotating a feed consisting of two parallel dipoles[7]

Although the measurements at 408 Mc/s showed some interesting details, the presence of interstellar Faraday rotation made interpretation of these details in terms of magnetic field structure impossible Measurements at other frequencies would be needed to obtain this interstellar Faraday rotation, thereby at the same time gaining additional information about the magnetic field The only results which yielded a positive determination of the intensity and polarization angle at a frequency different from 408 Mc/s are measurements made with the 210-ft Parkes telescope, of a rather limited part of the sky[7] These measurements showed that a large variation over small distances in the sky existed in the apparent spectral index. This might be due to an effect of depolarization, by which different regions would be observed at different frequencies Some measurements were also made at 178 Mc/s at Cambridge These observations showed the probable existence of polarized radiation at this frequency, but no intensity or polarization angle could be obtained[8]

To obtain some measurements at a frequency different from 408 Mc/s in the northern sky, one of us (C A M) designed a receiver with a centre frequency of 610 Mc/s During June 1963 this receiver was used in connexion with the 25-m radio telescope of the Netherlands Foundation for Radio Astronomy at Dwingeloo By using a larger bandwidth (3 6 Mc/s) than at 408 Mc/s (1 8 Mc/s), and by using two-channel detection, which utilizes all available information, a signal-to-noise ratio equal to that at 408 Mc/s was obtained, even though the intensity of the polarized radiation was roughly a factor three lower As, moreover, the spurious effects turned out to be also less by about a factor three, the reduction process as used to obtain the 408 Mc/s results could be maintained[3,4] As a test of the reality of the observed radiation, the observed polarization angles were plotted against the Faraday rotation expected for each measurement on the basis of a parabolic F_2-layer, for those points in the sky which were observed frequently for calibration purposes The ionospheric data used in this comparison were kindly put at our disposal by Drs H J A Vesseur of the Dutch Meteorological Institute, K N M I , at De Bilt One of these comparison plots is shown in Fig 1 Although the ionospheric Faraday rotation at 610 Mc/s is rather small (ref 9), a correlation between the two parameters is obviously present This shows that the observed signals are indeed due to a source beyond the Earth's atmosphere, and not merely caused by unknown instrumental effects[9]

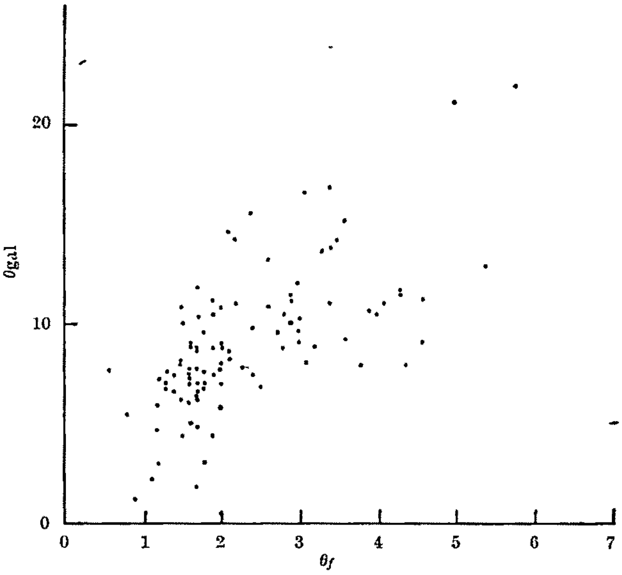

Fig 1 Comparison of the observed polarization angle (θ_{gal}) and the Faraday rotation expected on the basis of a parabolic F_2-layer (θ_f)

The results of the measurements are shown in Fig 2 The average internal mean error was 0 11° K for one measurement, but we suspect the presence of systematic errors in certain parts of the sky, which will not be eliminated by repeated measurements, of up to 0 3° K The observations were mainly restricted to those regions where a high polarization brightness temperature had been found at 408 Mc/s Some data about the points which were measured ten times or more are summarized in Table 1 The intensities and position angles for the same points at 408 Mc/s are included for comparison Combining the two sets of measurements, an apparent spectral index and an apparent Faraday rotation at 408 Mc/s can be deduced If we assume that the apparent Faraday rotation calculated in this manner represents the real interstellar Faraday rotation, the product $\overline{N H_{\parallel}} L$ can be calculated This product is shown in the last column of Table 1

The most pronounced feature on the map in Fig 2 seems to be a region in which the Faraday rotation is almost zero, and which extends from $l^{II} = 120°$, $b^{II} = -50°$ up to $l^{II} = 140°$, $b^{II} = +10°$ To the immediate left of this region the Faraday rotation is largely anticlockwise, while to the immediate right it is clockwise This would suggest that in this region the line of sight may be at

right angles to the direction of the magnetic field, while to the right of the region a component away from the observer and to the left a component towards the observer exist.

It may be noted that in the large region of high polarization between 120° and 155° longitude and 0° and +12° latitude the directions of polarization are much more parallel at 610 Mc/s than at 408 Mc/s As the Faraday rotation at 610 Mc/s is roughly equal to the differential rotation between 610 Mc/s and 408 Mc/s it must be expected that the original radiation over this entire field is practically parallel, and perpendicular to the galactic equator

Another remarkable fact is the spectral index, which for the majority of the observed points is about three, showing that, although the Faraday rotation is appreciable in some places, the observed intensities are not markedly influenced by it This indicates that probably the Faraday rotation does not exceed 180 degrees at 408 Mc/s, suggesting that either the magnetic field involved is fairly small, or that the radiation originates in the neighbourhood of the Sun

The region near the galactic north pole has a rather complicated structure, which may be due to the presence of the north polar spur It seems at the present moment to be impossible to disentangle the complicated structure of the galactic magnetic field by means of polarization observations at only two frequencies More measurements, and more accurate measurements, at other frequencies will be needed before any attempt can be made to prepare a map of the galactic magnetic field

We thank the staff of the Radio Observatory at Dwingeloo, who built and maintained the receiver and its digital equipment The reduction of the measurements was carried out on the electronic computer X1 of the Computing Centre of the University of Leyden The work was financially supported by the Netherlands Organization for the Advancement of Pure Research (Z W O)

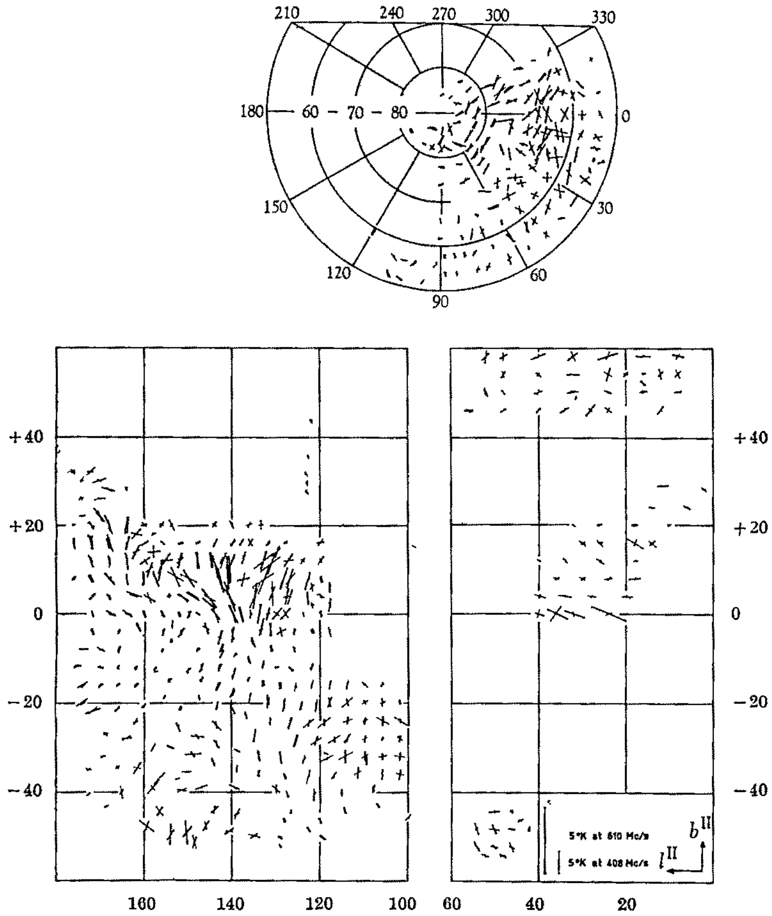

Fig 2 Intensities and position angles of the polarized radiation at both 610 Mc/s and 408 Mc/s

Radio and International Geophysical Research

In Dr R L Smith-Rose's excellent review of the achievements of radio studies in geophysical research[1] there appears a passage which might be misunderstood by those interested in practical ionospheric communications He says that research has shown it "to be desirable to use aerial systems which project the radiation at a greater angle of elevation than has hitherto been considered the most appropriate"

In fact, as a result of research, efforts are being made by communicators to radiate at lower angles than have been used in the past, so as to benefit from the secant law of ionospheric propagation Dr Smith-Rose's remark no doubt alluded to the hypothetical assumption of zero angle radiation which is adopted in drawing conventional frequency predictions for long routes

[1] *Nature*, **199**, 11 (1963)

I thank Mr Morris for pointing out that the passage in question may be somewhat ambiguous to those concerned with practical communications But the phrase quoted must not be read out of context with the rest of the paragraph I was, in fact, recording the conclusions reached in a study of electron density/height profiles and their application to high-frequency communication[1] I agree that some practical communication systems were designed to use higher angles of transmission and reception, and this means that improved results would probably be obtained by reducing the angle of elevation, having due regard to the frequency in use and the range of communication in question

PHYSICS

Use of an Electron Beam for detecting Superconducting Domains of Lead in its Intermediate State

SUPERCONDUCTING domains have been detected in lead by means of an electron beam technique previously used to detect magnetic domains[1] A spectroscopically pure cylinder of lead, 1 1 cm long and 0 28 cm in diameter, was mounted with its axis vertical in a modified horizontal electron diffraction camera A 20-kV electron beam was focused about 15 cm from the cylinder and was deflected at 50 c/s in a vertical direction by means of suitable coils, so as to produce an electron shadow of the lead cylinder Fig 1c shows a photograph of a shadow taken with the lead in its normal state In this case the smooth edge is merely a geometrical projection of part of the curved surface of the cylinder The cylinder, which could be heated electrically by a non-inductively wound heater, was attached to the outside of a metal vessel containing liquid helium A uniform magnetic field could be applied to the lead by means of a pair of small Helmholtz coils These were mounted symmetrically on either side of the lead with their common axis horizontal and perpendicular to the mean direction of the undeflected electron beam

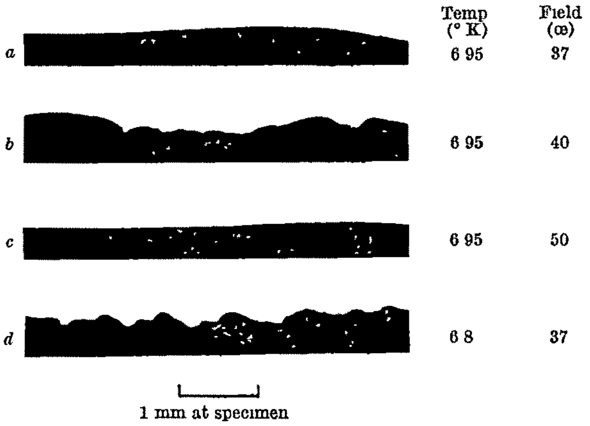

Fig 1 Electron shadows of the surface of a lead cylinder, showing lead in the following states (*a*) superconducting, (*b*) intermediate, (*c*) normal, (*d*) intermediate

The electron shadow shown in Fig 1*a* was taken after the applied field had been increased from zero to 37 œrsteds When the field was further increased to 40 œrsteds the shadow edge ceased to be smooth (Fig 1*b*) It became smooth again for fields in excess of about 50 œrsteds (Fig 1*c*)

These observations are consistent with the following explanation At and below 37 œrsteds the lead was superconducting At 40 œrsteds the lead transformed to the intermediate state[2] in which alternate lamellæ of superconducting and normal lead were perpendicular to the axis of, and approximately periodically distributed along, the cylinder Since the applied field was expelled from the superconducting parts, a concentration of magnetic flux occurred in the normal regions The resulting periodic distortion of the previously uniform field led to the 'corrugated' electron shadow shown in Fig 1*b* Above about 50 œrsteds the intermediate state transformed to the normal state Taking 50 œrsteds as the critical field this would indicate that the results so far described were obtained with the lead at about 6 95° K (ref 2)

Fig 1*d* was obtained by cooling the lead in a field of 37 œrsteds from a temperature at which the cylinder was in its normal state to 6 8° K The irregularities in the electron shadow may again be explained by assuming that the applied field was distorted because the lead was in its intermediate state The distance between adjacent minima on the shadow in Fig 1*d* corresponds to distances varying from 0 08 to 0 29 mm at the specimen It follows that these distances give the order of the periodicity of the superconducting domains in lead under the conditions of the experiment The variation of this periodicity as a function of applied field and temperature has not yet been studied in detail A full account of the work and details of the apparatus will be published in due course

Gamma-ray Spectrometric Determination of Cæsium-137 in Sea-water by using Ammonium Molybdophosphate as Scavenger

A NUMBER of methods have been proposed for determining very low concentrations of cæsium-137 in sea-water by γ-ray spectrometry The sodium potassium cobaltinitrite method[1,2] and the nickel ferrocyanide method[3] were proposed by several workers for identifying traces of cæsium-137 Special considerations should be made on the purity and the size of the cæsium sample to be counted and the simplicity of the procedure to be suited for shipboard operations

The ammonium molybdophosphate method was used by Yamagata and Yamagata[4] originally for the radiochemical determination of cæsium-137 in biological materials, the precipitate of ammonium molybdophosphate being made *in situ* in a sample solution Meanwhile, the work of Smit[5] revealed the ion-exchange properties of ammonium molybdophosphate, and the use of solid ammonium molybdophosphate by adding to sample solution as a specific scavenger was made by Yamagata *et al* [6] in the neutron activation analysis of common cæsium and by Miyake *et al* in the determination of cæsium-137 in sea-water[7]

The best conditions for scavenging concerning temperature, acidity, the quantity of carrier cæsium and the quantity of ammonium molybdophosphate were checked by Yamagata *et al* [6] The experiments on a small scale showed about 0 1 per cent quantity of the ammonium molybdophosphate (wt /vol) was enough to recover more than 95 per cent of cæsium labelled with cæsium-137 in sea-water in acid conditions However, the large-scale operations on 100–200 l of sea-water by this method resulted in only 70–80 per cent of recoveries with the addition of 5 mg quantity of carrier cæsium per litre[8] The reduction in recoveries might have been caused by losses in the large-scale operations, and the addition of carrier cæsium as well because of the limited ion-exchange capacity of the ammonium molybdophosphate

To overcome the difficulties involved in the addition of appreciable amount of carrier cæsium for checking the recovery in full-scale operation, the radioactive cæsium-132 was examined for its use as a spike This radioisotope was produced by a (γ, *n*) reaction on the purified cæsium chloride using a linear accelerator at the Japan Atomic Energy Research Institute It had specific activities of about 1 mc /g cæsium when used as a spike and several hundred μμc were applied to 100 litres of sea-water sample This means the addition of only less than 1 μg of the stable cæsium to 50 μg of naturally occurring cæsium in the sea-water, as compared with 500 mg of carrier cæsium added by other workers[6]

The radiochemical purity of the spike cæsium-132 was checked by following up the decay over the period of ten half-lives and also by measuring γ-ray spectra Half-life was measured as 6 8 days and no characteristic photopeaks other than those attributed to cæsium-132 were observed

Surface waters were collected in the Sagami Bay, off Enoshima, at 35° 16′ N , 139° 28′ E on May 14 and transported to the laboratory To 100-l aliquot of the sample were added several hundred $\mu\mu$c of standard spike solution of cæsium-132 and the mixture agitated mechanically for half an hour after the addition of 1 l. of concentrated hydrochloric acid and 90 g of the solid ammonium molybdophosphate After settling overnight the supernatant liquid was siphoned off and the scavenger collected in a plastic assay cylinder, 3 in in diameter After the scavenger had been allowed to settle it was placed on top of a sodium iodide crystal (3 in × 3 in) and the γ-ray spectrum taken for 100 min by using a 256-channel pulse height analyser

Recovery of spike cæsium-132 was determined on the characteristic photo-peak of 0 67 MeV by comparing with the spectrum from adding known amounts of spike solution to the scavenger The contribution of cæsium-137 activity (0 66 MeV) in the sample was estimated as approximately 3 per cent and this was subtracted from the results after the measurement of cæsium-137 Duplicate independent scavengings showed 91 and 97 per cent of recovery

Two months were required for allowing the spike activity to decay, and then the γ-spectrum was taken for 1,000 min to determine the activity of cæsium-137 in the spectral region almost identical to that for the determination of cæsium-132 Comparison made with the spectrum from adding known amounts of standard cæsium-137 to the scavenger resulted in 20 ± 5 $\mu\mu$c per 100 litre seawater The spike activity in the sample was calculated as being less than 1 $\mu\mu$c , which was negligibly small compared with the errors involved in the activity measurement

One of the advantages of this spike method of determination would be the use of identical spectral region around 0 66–0 67 MeV for both recovery and activity measurements, making feasible the use of only a single-channel pulse height analyser Adsorption of potassium to the ammonium molybdophosphate was too small to affect the γ-ray background, and the difficulty involved in the sodium potassium cobaltinitrite method[2] would be overcome Contamination of the ammonium molybdophosphate with radionuclides other than cæsium-137 which may be present in sea-water was checked by tracer experiments Table 1 summarizes the results Only zirconium–niobium-95 would interfere with the determination by use of a single-channel analyser if appreciable amounts of these nuclides are present in sea-water

Table 1 CONTAMINATION OF THE AMMONIUM MOLYBDOPHOSPHATE WITH OTHER RADIONUCLIDES IN ACID MEDIA (0 1 G AMMONIUM MOLYBDOPHOSPHATE IN 100 ML SEA-WATER)

Tracer	Contamination (% of applied radioactivity)	Specific activity of the tracer (c /g)	Gamma-ray energy (MeV)
$^{51}CrO_4$ (II)	1 6	51 6	0 33
^{54}Mn (II)	< 0 14	1 0	0 84
^{60}Co (II)	< 0 40	5 0	1 17, 1 33
^{65}Zn (II)	< 0 10	1 2	1 12
^{89}Sr (II)	< 0 50	C F	
^{91}Y (III)	2 3	C F	
^{95}Zr–^{95}Nb	11 8	C F	0 72, 0 77
^{106}Ru–^{106}Rh	< 0 17	C F	0 52
^{144}Ce (III)	0 38	C F	0 13

Table 2 CONCENTRATION OF CÆSIUM-137 IN THE COASTAL WATERS OF JAPAN

Date collected	Position	Cæsium-137 ($\mu\mu$c /l)
May 14, 1963	Sagami Bay 35° 16′ N , 139° 28′ E	0 2 ± 0 05
July 30, 1963	Sasebo Harbour 33° 08′ N , 129° 43′ E	0 6 ± 0 1
August 1, 1963	Kure Harbour 34° 06′ N , 132° 37′ E.	0 6 ± 0 1
August 3, 1963	Tsuruga Bay 35° 44′ N , 136° 03′ E	0 7 ± 0 1

Finally, considering the high efficiencies with which the cæsium-137 in sea-water can be carried by the proposed method and the errors involved in activity measurements, neither addition of carrier cæsium or spike, nor correction of the results for recovery would be necessary

The simplicity of the method makes it convenient for processing samples of large volume If other fission activities or corrosion products, such as cobalt-60, are to be measured on the same sample, the manganese dioxide method proposed by Yamagata *et al* [9] may be successfully applied preceding the ammonium molybdophosphate scavenging Table 2 summarizes the results of determination of cæsium-137 by using the proposed method

Stimulated Optical Emission of a Terbium Ion Chelate in a Vinylic Resin Matrix

RECENTLY, the observation of optical maser action of a europium chelate (europium *tris*[4,4,4-trifluoro-1-(2-thienyl)-1,3 butanedione]) in polymethylmethacrylate (Eu TTA in PMMA) was reported[1]

This communication describes the probable stimulated emission of the terbium-substituted counterpart of the material system described here, that is, Tb TTA in PMMA This compound was prepared by the method described by Crosby *et al* [2] The Tb^{3+} ion was excited by optically pumping into the absorption band of the chelating molecules (TTA), which is approximately in the wave-length interval 3200 Å–3700 Å (maximum excitation at 3350 Å) The absorption coefficient of this chelate's excitation band is comparable with that observed for Eu TTA excitation band[1] approximately 10^6 mole^{-1} cm^{-1} At 77° K, energy is efficiently transferred from the metastable triplet-state energy-levels of the TTA molecule to the resonance energy-level $^5D_4$ of the Tb^{3+} ion[2] I have observed that the fluorescence of Tb TTA in PMMA is quenched at 300° K

Strong fluorescence of the Tb^{3+} ion occurs at approximately 5450 Å due to a transition from the $^5D_4$ to the $^7F_5$ energy-level The terminal $^7F_5$ energy-level of this transition is known to be about 2100 cm^{-1} above the ground state The fluorescence spectrum of Tb TTA in PMMA is strongly correlated in wave-length with that of anhydrous terbium chloride, which has its strongest line $\simeq$ 5450 Å The normal fluorescence lifetime and total line-width for the 5450 Å line of Tb TTA in PMMA was measured to be $\simeq$ 0 7 m amp and 60 Å, respectively, at 77° K

In the experiments we carried out several short, straight, polymethyl-methacrylate fibres doped with a Tb TTA concentration of approximately 0 08 per cent of the weight of the PMMA The fibre for which results are presented by Figs 1–3 was approximately 0 75 mm in diameter by 60 mm in length, both ends of the fibre were polished and one end was silvered Other small fibre samples (terbium in TTA) showed similar behaviour

The experimental apparatus was assembled as follows the fibre was immersed in liquid nitrogen inside of an optically transparent, cylindrical 'Pyrex' Dewar A tubular absorption filter composed of 'Corning 7–54' glass was interposed between the fibre and the inside wall of the Dewar The 'Corning 7–54' filter permitted the desired pumping radiation to reach the fibre and, at the same time, reduced the pump radiation component at 5450 Å In addition, by rejecting the infra-red radiation of the flash-lamp, the filter reduced cooling problems and minimized thermal decomposition of the terbium TTA A helical, xenon flash lamp, which surrounded the Dewar, provided the pumping radiation The radiation from the fibre was detected with a 6,199 photomultiplier A monopass interference filter (maximum transmission at 5450 Å) was interposed between the photomultiplier cathode and the output end of the fibre An opaquely coated light pipe to guide the radiation from the end of the fibre to the photomultiplier, plus the action of the filters, reduced the amount of pump radiation (leakage) incident on the photodetector The light pipe also served the function of allowing the entire fibre to be immersed in liquid nitrogen To eliminate the possibility of spurious response in our apparatus, I substituted undoped fibres of the same dimensions in place of the doped fibres I observed only a moderate flash-lamp leakage in the output

The radiation output versus time curves observed for the fibre described here are shown for three different pumping-levels in Figs 1–3 Note that sufficient pumping leads to distortions of the normal fluorescence decay curve We interpret this to be evidence for stimulated emission Comparison of these photographs with those of europium TTA in PMMA fibres tested in our apparatus indicate very similar behaviour To corroborate that the distortion of the fluorescence decay curve represents stimulated emission, I am at present measuring the coherence properties on the output radiation

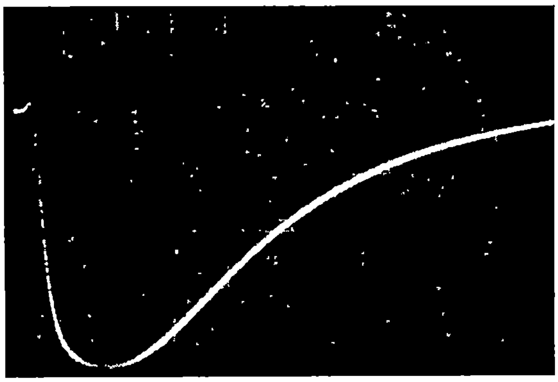

Fig 1 Normal fluorescence decay at 50-joules input Sweep 200 μs/cm

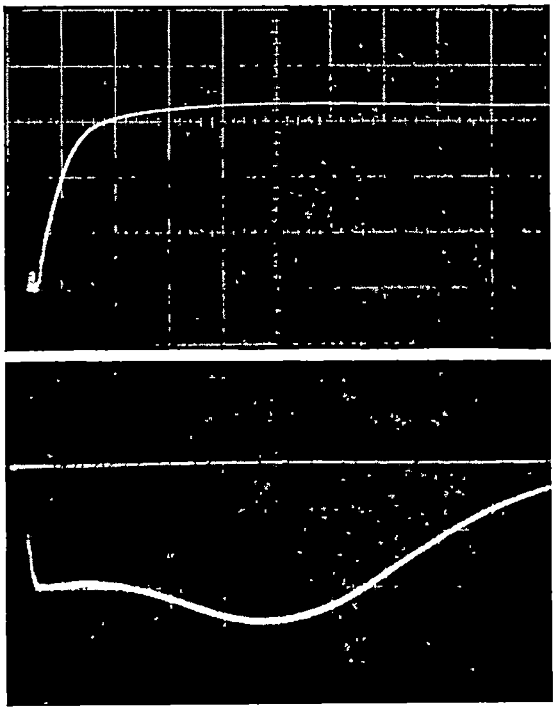

Fig 2 Upper, pump light at 225-joules input, lower, evidence of near threshold stimulated emission at 225 joule input Sweep 200 μs/cm Vertical amplifier gain is half that used in Fig 1

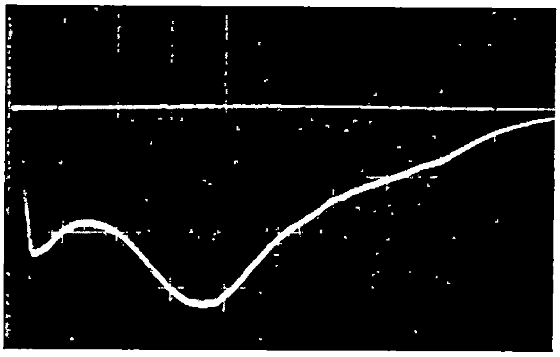

Fig 3 Evidence of stimulated emission at 400-joules input Sweep 200 μs/cm Vertical amplifier gain equal to half that used for Fig 1 The pump light outputs for Figs 1 and 3 (not shown) were similar in shape to the flash-lamp output of Fig 2

I am indebted to the late Dr B Herzog, of this laboratory, for invaluable discussions and advice, and for encouragement and support Furthermore, I thank William DeLaCruz and S L McCall for performing the experiments and in designing some of the experimental apparatus

Axial Migration of Particles in Poiseuille Flow

We have extended recent observations of the radial movements of single rigid[1,2] and deformable[3] spheres suspended in Newtonian liquids flowing through straight circular tubes to include other particle shapes and visco-elastic fluids

The experiments in Newtonian liquids were conducted as before[3,4] using single rigid spheres, rods and disks of the same density as the liquids but flowing at particle Reynolds numbers (Re_p) between 3×10^{-4} and 7×10^{-3} instead of less than 10^{-6} The tubular pinch effect previously observed with rigid spheres[1,2] at these Re_p was also exhibited by the rods and disks Particles placed initially near the tube-wall migrated inwards, while particles near the tube axis moved outwards until an equilibrium radial position (r) close to one-half the tube radius (R) was reached (Fig 1) For a given particle shape, the rate of radial migration increased with increasing flow rate, particle size and radial displacement from the equilibrium position Furthermore, rods and disks assumed limiting rotational orbits which were independent of the conditions of initial release The long axis of the rods and the faces of the disks became oriented in planes passing through the axis of the tube, corresponding to spherical elliptical orbit constants $C = \infty$ and 0 respectively[4], these are the orbits in which the particles make the maximum contribution to suspension viscosity[5] in Couette flow At low Re_p ($< 10^{-6}$) the radial positions and orbit constants of single rigid rods and disks remained

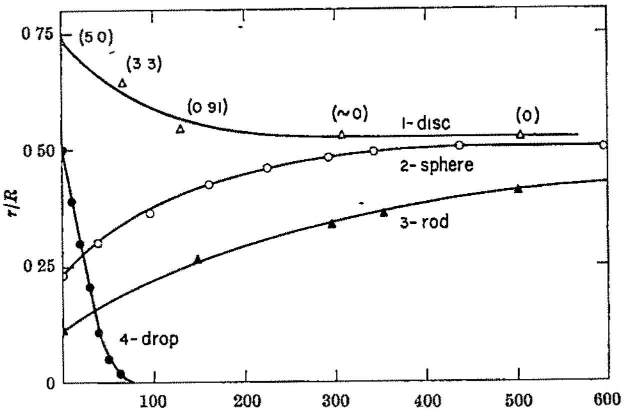

Fig. 1. Radial migration inwards (curve 1) and outwards (curves 2 and 3) to the equilibrium position $r/R = 1/2$ approximately, exhibited by spheres, rods and disks at high Re_p ($> 10^{-3}$) when suspended in polyglycol oils flowing through a tube $R = 0.2$ cm. The curves are: (1) polystyrene disk of radius 0.034 cm having an initial orbit constant $C = 5.0$, the numbers in parentheses indicating the decrease in C with radial distance and time; (2) polystyrene sphere of radius 0.050 cm; (3) nylon rod of length 0.11 cm. The steady inward migration to the tube centre of a glycerol drop in a polyglycol oil mixture, viscosity ratio suspended phase/suspending phase = 10, is shown by curve 4

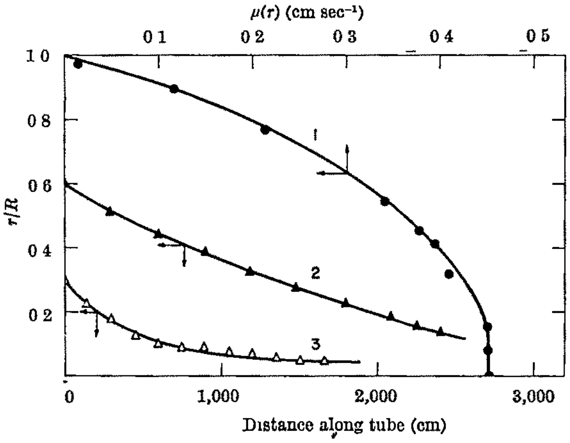

Fig. 2. Inward radial migration of 'Plexiglass' spheres in viscoelastic fluids flowing through a tube $R = 0.3$ cm at low Re_p ($< 10^{-6}$). Curve 1 shows the velocity profile, blunted near the tube centre, of a 6 per cent by weight solution of polyisobutylene in 'Decalin'. The inward migration to the central region of no shear of spheres of radii 0.016 and 0.021 cm suspended in the same solution is shown by curves 2 and 3 respectively

fixed at their initial values[4]. The drift in C and r at higher Re_p presumably are related effects due to inertia[6].

In striking contrast to rigid particles, liquid drops and elastomer filaments, which were deformed by the shear field in the tube, migrated inwards to $r = 0$ just as they did at low Re_p (refs. 3, 4). This behaviour was shown by liquid drops having a viscosity as high as 10 times that of the suspending medium (Fig. 1). When the ratio reached 50, and the drop deformation appeared negligible, the behaviour was as for rigid spheres, that is, no migration at low Re_p and migration to $r/R = 1/2$ at high Re_p. Thus the migration due to deformation[3,4] can dominate that due to inertia, and vice versa.

Inward migration of rigid particles occurred in the viscoelastic fluids at low Re_p ($< 10^{-6}$). Solutions of 3–6.3 weight per cent polyisobutylene ('Vistanex *L*-100', Enjay Chemical Co.) in decahydronaphthalene ('Decalin'), which have been well characterized rheologically[7], were used as the medium. As expected from the decrease in apparent viscosity with increasing rate of shear, the velocity profile $u(r)$ across the tube, instead of being parabolic as with the Newtonian liquids, was blunted in the central regions (Fig. 2). Rigid spheres, rods and disks placed near the wall rotated and migrated inwards to radial positions at which the velocity profile was nearly flat (Fig. 2). The rate of migration increased with r and particle size. During migration, rods and disks drifted into rotational orbits corresponding to $C = 0$ and ∞ respectively; these orbits correspond to *minimum* energy dissipation in Couette flow and are in agreement with Saffman's theoretical prediction and observations for rigid spheroids in a non-Newtonian fluid of the type used[8]. Particles in the flat portion of the profile, where the velocity gradient was zero, neither rotated nor moved radially. The particle migration observed in these experiments may arise from the combined action of normal stresses in the fluid and the variation in velocity gradient across the particle.

These experiments reveal three distinct mechanisms for radial migration during the flow of suspensions through tubes of which only one, that due to deformation at low Re_p, has been explained with any degree of completeness[4]. It is possible that there are additional mechanisms, especially at concentrations at which appreciable particle interaction can occur. These phenomena are of interest in connexion with the development of particle-free peripheral zones in the flow of various suspensions such as pulp fibre suspensions and blood through tubes.

This investigation was supported (in part) by U.S. Public Health Service research grant *H*-5911 from the National Heart Institute of the United States Public Health Service.

Secondary Electron Emission of Evaporated Titanium Films

IN our recent communication[1] we attributed the different secondary emission characteristics of oxidized titanium sheet and oxidized titanium films to the irregular surface on the sheet material influencing the incidence of the primary electron beam. However, we incorrectly stated that raising the incident angle of a primary electron beam should lower the value of the primary electron energy at which the secondary electron emission coefficient of a target reaches a maximum value. In fact the reverse is true, that is, raising the incident angle should increase the value of V_{max} (ref. 2). Our experimental results are not affected by this error, but the relation between the V_{max} for the oxidized titanium sheet and titanium films cannot be attributed to incidence.

We thank Dr. N. Ray Whetten of the Physical Electronics Research Laboratories, General Electric Co., United States, for bringing this to our attention.

ENGINEERING

Cleavage Fracture of Polycrystalline Aggregates

Both Cottrell[1] and Petch[2] consider that the fracture process is divided into two parts (1) the formation of a crack nucleus by dislocation coalescence, (2) the growth of this crack until it reaches a critical size when cleavage fracture spreads catastrophically Using the well-established relationship between the lower yield stress and grain size[3] they show that fracture should just be able to occur at the yield point when

$$\sigma_y k_y d^{1/2} = \beta\mu\gamma \qquad (1)$$

where σ_y is the lower yield stress, k_y is a grain size parameter related to the stress required to unpin a dislocation, β is a mechanical restraint factor, μ is the shear modulus and γ is the effective surface energy of the fractured faces The effective surface energy, γ, required to produce cleavage fracture in a correctly orientated grain includes a plastic work term and will be larger than the true surface energy However, it will be smaller than the specific energy G_{1c} (called the plane strain fracture toughness by Irwin[4]) required to propagate the fracture through a large number of randomly orientated grains Thus the size of the microcracks predicted by the Cottrell model[1] (using the effective surface energy γ) is an order of magnitude smaller than those observed by Hahn *et al*[5] Microcracks can only grow larger than one grain under the yield stress given by equation (1) if there are adjacent grains the orientations of which are favourable Therefore only a small proportion of the microcracks formed will be able to grow large enough to enable the energy release to be sufficient for fracture propagation through a randomly orientated structure

If, in a plain tension specimen, the probability that any one grain is favourably orientated with respect to the applied stress is p and the critical crack-length for initiation of a fracture through randomly orientated grains is nd, then the probability for the growth of such a crack at the yield stress is p^n Thus the Cottrell model[1] will give the criterion for cleavage fracture at the yield stress in plain specimens provided that the number of grains in the specimens is greater than p^{-n}

In a notched specimen, the stress is non-uniform and only a limited number of grains will be subjected to the yield stress given by equation (1) Near the root of the notch the stresses will be of the order

$$\sigma = \frac{K}{\sqrt{2\pi r}} \qquad (2)$$

where K is the stress intensity[6] and r the radial distance from the root of the notch Only within a radius of

$$r = \frac{K^2}{2\pi\sigma_y^2} \qquad (3)$$

or

$$r = \left(\frac{Kk_y}{\beta\mu\gamma}\right)^2 \frac{d}{2\pi} \qquad (4)$$

will the stress be greater than σ_y The number of grains in this region is

$$N = \frac{1}{\pi^2}\left(\frac{Kk_y}{\beta\mu\gamma}\right)^4 \qquad (5)$$

If the mean of the probability of favourable grain orientated over the highly stressed region is p and the critical crack length is again nd, cleavage fracture at the lower yield stress will occur only if

$$N = \frac{1}{\pi^2}\left(\frac{Kk_y}{\beta\mu\gamma}\right)^4 > p^{-n} \qquad (6)$$

There has not been a great deal of experimental work on the effect of grain size in notched specimens The results that there are do indicate that cleavage fracture is dependent on grain size However, there is some doubt[7] that the effect is entirely due to grain size *per se* and not to changes in the internal structure brought about by the treatment that results in a finer structure Thus it is not certain that the inequality (6) is necessarily satisfied and in certain cases the fracture strength need not be dependent on grain size This may mean that the fracture strength of electro slag welds with their very large grain structure may not be as low as previously thought

METALLURGY

Effects of High Pressure on the Strength and Structure of Martensites

Following the direct observation of fine-scale twinning ($\sim$100 Å spacing) in the martensitic structures formed by the rapid quenching of certain steels and other alloys[1], relationships between the incidence of twinning and the high mechanical strength of martensites have been postulated, explicitly in a qualitative strengthening model[2] and implicitly in a quantitative solution-hardening model[3] In view of the suggested importance of the twinning contribution to strength, an attempt has been made to test its validity by experiments on martensitic transformations in the iron–carbon and iron–chromium systems at high pressure and in the iron–nickel system at atmospheric pressure The experimental apparatus and techniques used have been described elsewhere[4]

In the Kelly–Nutting model[2], the rapid increase in martensite strength (beyond that attributed to solution hardening) and incidence of twinning with increasing carbon content are considered to arise from the effect of carbon in depressing M_s from above to below a critical temperature range for twinning (approximately 300°–220° C) which is essentially composition independent It has been demonstrated previously for the iron–carbon system that the temperature at which martensite formation begins on cooling (M_s) is depressed substantially at high pressure[4] Accordingly, if the twinning model were correct, the strength of martensite formed in all compositions which have their M_s depressed at a given pressure to below the critical temperature range should attain or approach that of fully twinned martensite formed at atmospheric pressure Microhardness measurements on a series of iron–carbon martensites formed at atmospheric pressure and at 42 kilobars are compared in Fig 1 At the high pressure, the lowest composition for which M_s is below the critical range is reduced from 0 75 down to 0 4 wt per cent carbon[4] However, the expected increase in hardness to high values characteristic of fully twinned martensites in this system (925 VPN) is not observed for the two alloys in this composition region Instead, the hardness of the 0 4 wt per cent carbon alloy increases to only 780 VPN and the higher carbon alloy to a similar value, that is, the hardness increase is smaller for the latter alloy Furthermore, the 0 08 wt per cent carbon alloy, even though it transforms above the critical range at 42 kilobars, exhibits an increase in hardness as large as that for the 0 4 wt per cent alloy The specimens of high-purity iron and the 0 75 and 1 2 wt per cent carbon alloys show only minor changes, this result suggests that any plastic deformation arising from quasi-hydrostatic conditions in the high-pressure cell does not contribute strongly to the hardness increases in the intermediate alloys

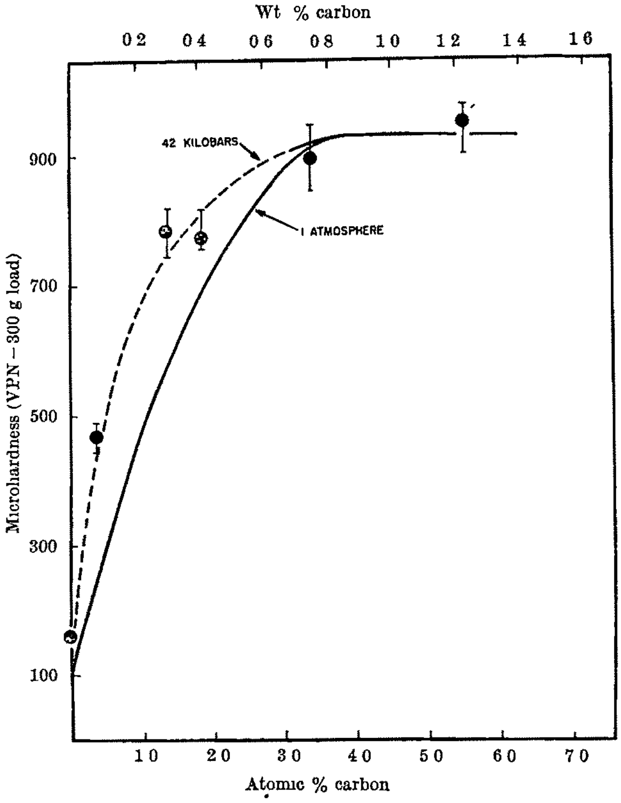

Fig. 1. Effects of pressure on hardness of martensites formed in iron–carbon alloys

The lack of hardness change for martensites containing more than 0.75 per cent carbon is consistent with the twinning model in that such martensites are normally fully twinned, so that further depression of M_s would not be expected to change the incidence of twinning. However, the hardness changes for the intermediate alloys are not in keeping with the model. Instead, it appears likely that the changes observed are attributable to a reduction in the loss of carbon from solution by self-tempering, that is, to an increase in solid-solution hardening. Self-tempering is not normally important in high carbon martensites, so that high pressure would not be expected to affect them, as is observed. Confirmation of this interpretation by transmission electron microscopy has not yet been possible because of difficulties encountered in preparing suitable thin-foils from the small specimens used in the high-pressure investigations.

In addition to the concept of a critical temperature range, the qualitative twinning model attributes a large twinning contribution to the strength of body-centred cubic martensites, in which the solution-hardening characteristic of tetragonal martensites containing carbon is absent. In the iron–nickel system, body-centred cubic martensites containing finely spaced twins can be formed only in alloys containing more than some 20 atomic per cent nickel. Alloys lower in nickel form the so-called 'massive' structures[6], which do not exhibit internal twinning. It is to be noted that over this composition range the M_s is indeed above the suggested critical range for twinning. In the iron–chromium system, the high-temperature face-centred cubic phase (γ) is restricted to a loop-shaped phase field with a maximum chromium content of 13.5 atomic per cent chromium, and all alloys quenched from within this field exhibit 'massive' structures. At high pressure, the extent of the γ-phase field is extended so that, in principle, it should be possible to quench alloys sufficiently high in chromium to have an M_s below the critical range. Such quenched alloys would be expected to show twinned martensitic structures. Thus, an examination of the iron–chromium system at high pressure should permit an additional test of the validity of the concept of a critical range for twinning. Furthermore, observation of the changes in hardness with solute content for quenched iron–chromium and iron–nickel alloys provides a test of the twinning contribution to strength, since a discontinuous increase in strength should be observed on reaching compositions at which twinned martensites are formed.

In Fig. 2, the increase in the extent of the γ-field in the iron–chromium system at 42 kilobars is shown, as measured from metallographic examination of equilibrated and quenched specimens and continuous electrical resistance measurements. At this pressure, the maximum chromium content of the loop is increased to ~21 atomic per cent chromium. These measurements confirm and extend the previous measurements shown of the depression of the γ-field in low-chromium alloys[5]. The composition dependence of the hardness of alloys quenched from within the loop region at 42 kilobars does not exhibit a discontinuity, although there is a possible indication of the beginning of one for the 20 atomic per cent chromium alloy. However, the measured M_s values indicate that even for the higher chromium alloys the transformation temperature is depressed only into and not below the critical range. The structures are 'massive' except for the 20 atomic per cent chromium alloy, which has an acicular structure. As for the iron–chromium alloys, replica electron microscopy proved inadequate to confirm the nature of the structure, and transmission microscopy has not yet been possible. It is clear that in the iron–chromium system a higher pressure is needed to depress adequately the transformation temperature, either directly or by the use of alloys still higher in chromium.

In Fig. 3, the composition dependence of hardness for a series of iron–nickel alloys quenched into liquid nitrogen

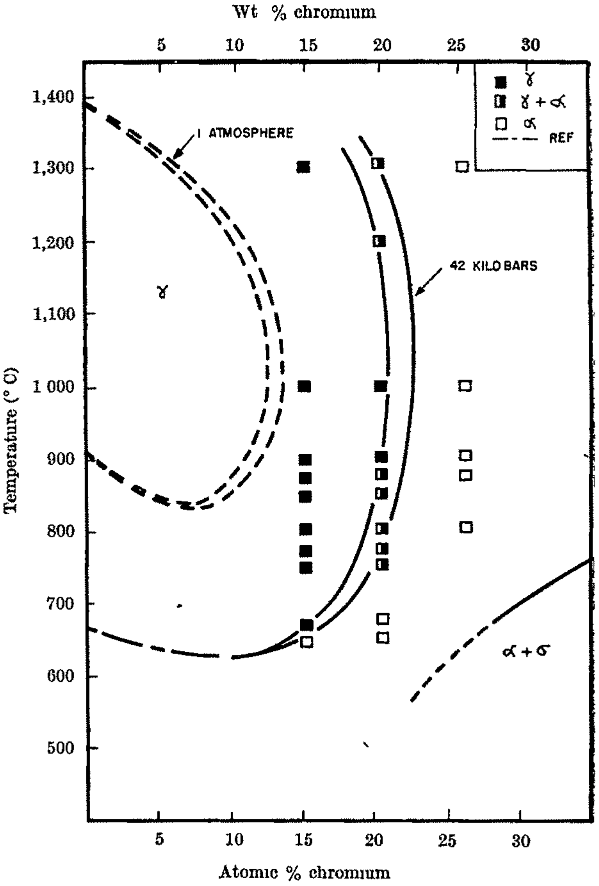

Fig. 2. Shift of γ-loop in iron–chromium system at 42 kilobars

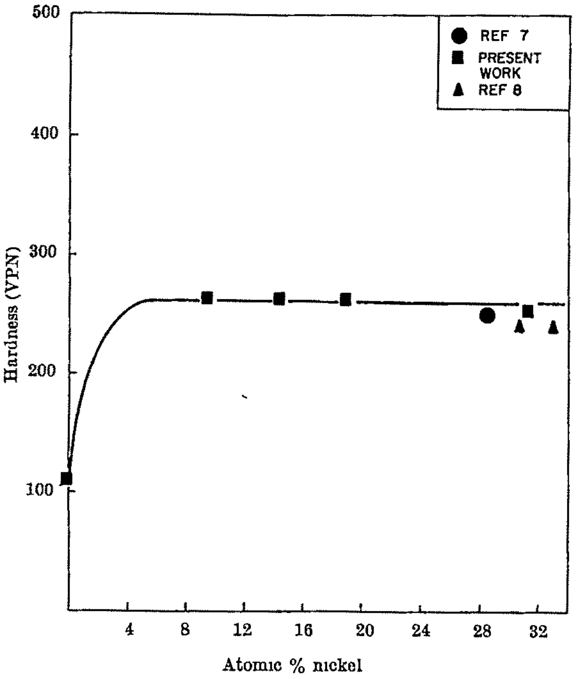

Fig 3 Effect of nickel content on hardness of iron–nickel alloys transformed by quenching at atmospheric pressure

(−196° C) to ensure completion of transformation is shown, together with reported data for high-nickel twinned martensites[7,8] The transition between massive and twinned martensitic structures with increasing nickel is well established[6], and the lack of any discontinuity in hardness is clear evidence of the lack of any singular contribution to strengthening from the presence of fine internal twinning It is interesting to note that the maximum hardness attained by twinned iron–nickel–carbon martensites[9] is only 630 VPN, compared with 260 VPN for twinned iron–nickel martensite and 925 VPN for iron–carbon martensites Thus, the presence of nickel strongly reduces the hardness of carbon martensites, even in the presence of internal twinning

In the Winchell–Cohen model of the strengthening of carbon martensite by solution hardening[3], the fine spacing of internal twins is considered to define the effective length of active dislocation line—an important parameter in the model In iron–carbon alloys and plain carbon steels, the proportion of internally twinned martensite plates is small up to some 0 34 weight per cent carbon, and complete twinning occurs only above 0 8 weight per cent carbon As the greater part of the hardness increase with increasing carbon occurs by 0 34 weight per cent carbon, the applicability of such a model to carbon martensites in general is doubtful Furthermore, since the present results show that structural twinning *per se* is not important to strength in iron–nickel martensites, the validity of using the twin spacing to define an effective length of dislocation in iron–nickel–carbon martensites is in question

It is concluded that the presence of fine structural twins does not make an important contribution, either directly or indirectly, to strength in tetragonal or body-centred cubic martensites in iron-alloys Structural twinning is an important part of the mechanism of martensite formation[1] and mechanical twinning is important in limiting the maximum strength which can be attained[10] However, the principal strengthening mechanisms operative during the initially rapid increase in strength with increasing carbon content must depend primarily on a solid-solution hardening mechanism, possibly one similar to that suggested by Winchell and Cohen, but in which the effective dislocation length is defined by a structural feature other than twinning

CHEMISTRY

Role of Free Radicals in the Photo-oxidation of Fe^{+2} in Acidic Solutions of Ferrocyanide

Neutral solutions of $K_4Fe(CN)_6$ have been known to become alkaline when irradiated by ultra-violet light[1–3] It has been suggested that photolysis of $Fe(CN)_6^{-4}$ first takes place to give $Fe(CN)_6^{-3}$ and $(CN)^{-1}$, and the latter then hydrolyses, producing free alkali

$$Fe(CN)_6^{-4} \xrightarrow[h\nu]{} Fe(CN)_5^{-3} + (CN)^{-1} \quad (1)$$

$$(CN)^{-1} + H_2O \rightarrow (HO)^{-1} + HCN \quad (2)$$

$$Fe(CN)_5^{-3} + H_2O \rightarrow [Fe(CN)_5\ H_2O]^{-3} \quad (3)$$

When the light source is cut off, all the three reactions are reversed and the original *p*H is restored unless irradiation has been far too prolonged[2]

We have found quite a different effect of ultra-violet light on $Fe(CN)_6^{-4}$ under acidic conditions Percolation of dilute solutions (about 2 g/l) of $K_4Fe(CN)_6$ through beds of the strong acid ion-exchanger, '*IR*–120', gave solutions which had a *p*H of about 1 5 When freshly prepared, they had a straw colour which slowly changed to light blue in diffuse sunlight Irradiation with ultra-violet light from a Philips mercury discharge lamp very soon gave an intense blue colour The blue substance has been identified as ferri-ferrocyanide which came down as a precipitate on standing

The composition of the acidic solutions before irradiation is determined mainly by the following three equilibria

$$H_4Fe(CN)_6 \rightleftarrows 4H^+ + Fe(CN)_6^{-4} \quad (4)$$

$$Fe(CN)_6^{-4} \rightleftarrows Fe^{+2} + 6(CN)^{-1} \quad (5)$$

$$CN^{-1} + H^{+1} \rightleftarrows HCN \quad (6)$$

Calculations made from known values of the instability constant[3] of $Fe(CN)_6^{-4}$ and the dissociation constant of HCN (ref 4) showed that, at a *p*H of about 1 5, very little $Fe(CN)_6^{-4}$, as such, would be present, and the predominant species would be Fe^{+2} and HCN The freshly prepared acidic solution, however, titrated as a strong acid Its *p*H titration curve (Fig 1) indicated four strong H^+ ions per Fe^{+2} ion During the titration, a gradual shift of equilibria (5) and (6) occurs and the solution titrates as $H_4Fe(CN)_6$, which is a strong acid and gives back $K_4Fe(CN)_6$ on complete neutralization

On irradiation photo-oxidation of the Fe^{+2} ions takes place and this gives the ferri-ferrocyanide Jortner and Stein[5,6] have shown that Fe^{+2} ions in acidic solutions of

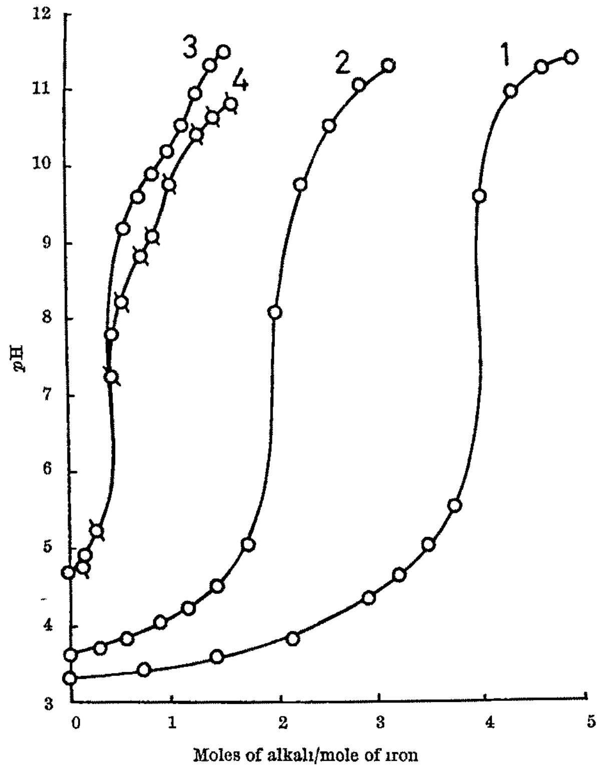

Fig 1 1, No irradiation, 2, 2-h irradiation, 3, 4-h irradiation, 4, 6-h irradiation

$FeSO_4$ are oxidized to Fe^{+3} under the influence of ultraviolet light We found, however, that the rate of oxidation of Fe^{+2} ions in an acidic solution of $FeSO_4$ was only about 5 0 per cent of the rate at which ferri-ferrocyanide was formed in an equimolar solution of $K_4Fe(CN)_6$ of the same *p*H Evidently, the mechanism of oxidation is not quite the same in the two cases We believe that, on irradiation, photolysis of HCN present in the acidic solutions of ferrocyanide first takes place to give H and CN radicals

$$\mathrm{HCN} \xrightarrow{h\nu} \mathrm{H}+\mathrm{CN} \qquad (7)$$

The CN radical then oxidizes Fe^{+2} to Fe^{+3}, either directly, or through a water molecule

$$\mathrm{CN}+\mathrm{Fe}^{+2}\rightarrow\mathrm{Fe}^{+3}+\mathrm{CN}^{-} \qquad (8)$$

$$\mathrm{CN}+\mathrm{H_2O}\rightarrow\mathrm{HCN}+\mathrm{OH} \qquad (9)$$

$$\mathrm{OH}+\mathrm{Fe}^{+2}\rightarrow\mathrm{Fe}^{+3}+\mathrm{OH}^{-} \qquad (10)$$

The acidic solutions contained dissolved oxygen, in the presence of which the H atom (equation 7) oxidizes three Fe^{+2} ions

$$\mathrm{H}+\mathrm{O_2}\rightarrow\mathrm{HO_2} \qquad (11)$$

$$\mathrm{HO_2} + \mathrm{H_2O} + 3\mathrm{Fe}^{+2} \rightarrow 3\mathrm{Fe}^{+3} + 3\mathrm{OH}^{-} \qquad (12)$$

Jortner and Stein also used equations (11) and (12) to explain photo-oxidation of Fe^{+2} However, while their only source of H was $[Fe^{+2}(H_2O)_n]$, we have an additional and, apparently, a more efficient source, namely, HCN

The Fe^{+3} ions produced by reactions 8, 10 and 12 react with $Fe(CN)_6^{-4}$ to produce Prussian blue The overall reaction is

$$8\mathrm{H_4Fe(CN)_6}+\mathrm{O_2}\rightarrow4[\mathrm{HFe(Fe(CN)_6}]+24\mathrm{HCN}+2\mathrm{H_2O} \qquad (13)$$

The titratable amount of the strong acid present in the solution decreases as irradiation proceeds and, ultimately, one-eighth of the strong acid remains (Fig 1) This is what one would expect from equation (13), if it is assumed that ferri-ferrocyanic acid is also a strong acid The presence of HCN, as a weak acid component, is clearly indicated by the titration curve obtained after complete irradiation However, the amount of HCN is smaller than what would be expected from equation (13) A large amount of HCN escapes during irradiation, the solution smelling strongly of the gas Some CN may also be lost by secondary reactions, for example, formation of $(CN)_2$

Concentration Effects in Measurements of Characteristics of Deoxyribonucleic Acid by Transport Methods

A CLOSE qualitative similarity between the mode of variation of the reduced viscosity ($\eta sp/C$) and that of the reciprocal of sedimentation coefficient ($1/S$) with concentration of deoxyribonucleic acid (DNA), pointed out recently[1], is also apparent from the following two expressions

$\eta sp/C$ at a finite low concentration C (gm/ml) may be related to its zero concentration value $[\eta]$ (the intrinsic viscosity in ml /g) as[2–5].

$$\eta sp/C=[\eta](1+k[\eta]C) \qquad (1)$$

where k is a dimensionless factor having a magnitude characteristic of the system[2] and is a function of all significant interactions (solute–solute and solute–solvent interactions) at this concentration[4]

$1/S$ at the concentration C may be related to its zero concentration value $1/S_0$, as [5–7]

$$1/S=(1/S_0)(1+\alpha[\eta]C) \qquad (2)$$

where α is a dimensionless factor$=Ks/[\eta]$, obtained empirically (see ref 5) It is reasonable to suppose that α is also like k, a function of all interactions in the system which are significant at this concentration

Both α and k decrease generally with increase of added sodium chloride in DNA solution[1,8] and in many cases with increase of rotor speed[9] and shear rate[8], respectively The numerical values of α and k obtained for large varieties of DNA samples in solvents containing sodium chloride of the order of 10^{-1} M are also comparable $\alpha=0\ 8\pm0\ 1$ (refs 5,10) and $k=0\ 5\pm0\ 2$ (ref 5), 0 77 (γ-ray irradiated DNA solutions[11]) Some of these values of k are again close to the theoretical[3] value of 0 73 for rod-like molecules There are, however, instances where DNA solutions in these solvents show lower or even zero values for α and k

To explain the observed results, a consideration of the factors (solute–solute and solute–solvent interactions in the system) contributing to the values of α and k may be made Three types of interactions between pairs of single macromolecules may be the contributory factors[4], (*a*) Long-range hydrodynamic interaction has always a positive contribution, (*b*) intermolecular attraction and repulsion may have positive or negative contribution, (*c*) formation of double molecules (the existence of which even though may be fleeting may provide equilibrium concentration of aggregates) in good and poor solvents, respectively, have negative and positive contributions

It is evident that, depending on the nature of solute and solvent, a combination of these three factors may result in either positive, zero or negative values of α and k Additional negative contribution may arise when α and k are dependent on rotor speed and shear rate, respectively When charge interactions, aggregation and shear rate or rotor speed effects are absent, the values of α and k will be positive and will be determined by long-range hydrodynamic interactions in the system Thus, for effectively uncharged macromolecules both $1/S$ and $\eta sp/C$ should be concentration dependent It may be interesting to note[12] that for uncharged solid spherical molecules, $k \approx 2$ was predicted theoretically[13] and was obtained experimentally[14] for polystyrene latex Also one may obtain $\alpha \approx 2$ for polystyrene latex from the solvent density corrected sedimentation data[14], and also for spherical molecules from the theoretical relation[6] between Ks and $[\eta]$ (using channel constant = 1 8). Thus, it appears that for spherical uncharged macromolecules the values of α and k may be the same If there occur interactions between the charged polymers and their counter-ions, resulting in polymer–polymer interactions of the types (*b*) and (*c*) described here, the applied forces arising out of shear rate or rotor speed may interfere with such interactions A relevant discussion pertinent to the magnitude of k in DNA solutions has been made in ref 8 Thus, when a DNA solution is such that its equilibrium composition readily alters with handlings involved in different experiments, the magnitude of the factor dependent on interactions will also alter

The effect of interactions at concentration C expresses itself in equation (1) as an increase in the effective volume of the particle[4] . There will be corresponding increase in the viscosity of the medium, so that one may write $(\eta sp/C)/[\eta] = \eta_{eff}/\eta_0 = 1 + k[\eta]C$, where η_{eff} is the effective viscosity of the medium arising out of all interactions at concentration C and η_0 is the viscosity of the medium (solvent) in absence of all interactions Defining a frictional coefficient f^c at concentration C which varies with η_{eff}, one can describe both the equations (1) and (2) as variation of frictional coefficient with concentration Thus, in general, one can express the concentration dependence of frictional coefficient for all transport processes[12] involving migration of macromolecules through viscous medium under the influence of infinitesimally small applied forces as

$$f^c = f^0(1 + \lambda[\eta]C) \qquad (3)$$

where f^0 is the frictional coefficient at zero concentration and λ is the factor the magnitude of which will be characteristic of all the interactions in the system at finite low concentration C of the macromolecule The concentration dependence of $1/D$ and $1/\mu$ (D = diffusion coefficient, μ = electrophoretic mobility) may be expressed on the basis of this equation (3), assigning a distinctive symbol in place of λ for each type of experiment

Thus, a general approach towards correlation of concentration effects observed in measurements of characteristics of DNA (which should also be applicable for other macromolecules or macro ions) by various transport experiments has been outlined here A similar attempt[15] proposes, in effect, that (instead of η_{eff} proposed here) the macroscopic viscosity of the solution is the function of all interparticle interactions On the basis of considerations presented in this communication one may judge the reasons for observed agreement and disagreement of such theory with practice, and also evaluate other explanations of concentration dependence of sedimentation coefficient[16] Considerations on the observed similarity between concentration dependence of S and of DNA charge mentioned earlier[1] and other details pertinent to this communication will be presented elsewhere

I thank the Council for Scientific and Industrial Research, India, for financial assistance and Prof N N Das Gupta, Dr A Sen and Dr P Mukerjee for advice

Quantitative Analysis of Ketosteroids by Means of Paper Chromatography

IN a previous paper[1] we described a method for the detection of small amounts of ketosteroids on chromatograms by means of DNPH The subsequent removal of the background colour enables the use of this method for quantitative analysis, as previously suggested A satisfactory solvent system, by which the hydrazones were eluted from strips and then determined by spectrophotometry, was found The procedure described here requires little time, and is suitable for routine estimations We have used this method in metabolic investigations *in vitro* as well as for measurement of the progesterone concentration in sheep's ovarian venous blood In both cases very satisfactory results were obtained

The procedure adopted for quantitative purposes was essentially like that previously described, except that the time of reaction with DNPH was shortened to 5 min. and the strips were neutralized in ammonia vapour instead of sodium carbonate solution Equally good results were obtained when washed in permanganate solution for 5 min without previous neutralization of the strips Whatman paper No 20 previously washed with methanol proved to be the most satisfactory one of all those tested The coloured hydrazone spots and respective blanks were cut out, then cut into small pieces and extracted four times at room temperature for 10 min each time, with a mixture of methanol–methyl acetate 1 4, the first portion of the eluent being 0 6 ml , the three subsequent ones 0 35 ml each It was necessary to use freshly dried strips, since storage caused an incomplete elution

The volume of the combined extracts was then adjusted to 1 5 ml immediately before measurement and the samples were read against appropriate blanks at 380 mμ The exact maximum absorption wave-length depended on the keto-group position of the particular steroid, for example, the peaks of pregnenolone, progesterone and testosterone lay at 365, 375 and 380 mμ respectively

The optical density was found to be 0 090–0 100 per μg progesterone, pregnenolone and testosterone have given respectively lower values

Glass cells of 1-cm light path and the Russian quartz spectrophotometer model *SF*-4 were used The calibration curves of pure steroids alone or with various lipid material added were usually linear in the range of 0 5–10 μg of diketones, or 1–20 μg monoketones, sometimes, however, they showed little curvature The minimum amount which can be determined is about 0 5 μg of progesterone The standard error expressed in extinction units was as high as 0 015 This value was found to be constant in the foregoing ranges of steroid quantities. This method was controlled radiometrically, using progesterone-4-^{14}C (The Radiochemical Centre, Amersham, England) and a current-flow gas counter, the loss of radioactivity during the procedure described did not exceed 5 per cent of the initial quantity added

Stability of *N*-Glycuronyl Amino-acids

In assessing the stability of the various possible linkages joining carbohydrates to amino-acid residues and in order to avoid base-catalysed acyl migration, we have synthesized *N*-(1,2 3,4-di-*O*-isopropylidene-D-galacturonyl)-glycine and its β-DL-phenylalanine analogue and examined their behaviour on hydrolysis The syntheses were effected by using as condensing agents either di*cyclo*hexylcarbodiimide[1], or tetraethylpyrophosphite[2]

1,2 3 4-Di-*O*-isopropylidene-D-galactose[3] was oxidized[4] with potassium permanganate and the crystalline potassium 1,2 3,4-di-*O*-isopropylidene-D-galacturonate obtained converted into the free acid by ethereal extraction of an acidified aqueous solution The acid (21 g) was added to a stirred solution of freshly prepared benzylglycinate (13 g) in diethyl phosphite (50 ml) Tetraethylpyrophosphite (22 g) was added and, after heating the stirred mixture at 100° for 10 min, it was poured into water The precipitate was washed with saturated aqueous sodium hydrogen carbonate and recrystallized from ethanol to yield benzyl *N*-(1,2 3,4-di-*O*-isopropylidene-D-galacturonyl)-glycinate (20 g), m p 101°–102°, $[\alpha]_D$ −89 5° (*c*, 1 0 in chloroform) (found C, 60 1, H, 6 6, N, 3 3 $C_{21}H_{27}NO_8$, requires C, 59 9, H, 6 4, N, 3 3 per cent)

Alternatively, glycine benzyl ester (1 39 g) was suspended in dry ether (100 ml) and a mixture of di*cyclo*hexylcarbodiimide (3 1 g) and 1,2 3,4-di-*O*-iso-propylidene-D-galacturonic acid (3 g) added After stirring at room temperature for 12 h, glacial acetic acid (3 drops) was added and the di*cyclo*hexylurea removed by filtration The residue (4 99 g) after evaporation of the filtrate was crystallized from ether to yield benzyl *N*-(1,2 3,4-di-*O*-isopropylidene-D-galacturonyl)-glycinate (1 21 g), m p 101°–102°, $[\alpha]_D$ −87 5° (*c*, 0 9 in chloroform), which was identical with the product described here Debenzylation could be effected with sodium and liquid ammonia to yield *N*-(1 2 3,4-di-*O*-isopropylidene-D-galacturonyl)-glycine, m p 212° (from ethyl acetate), $[\alpha]_D$ − 97 1° (*c*, 0 8 in chloroform) (found C, 51 0, H, 6 5, N, 4 25 $C_{14}H_{21}NO_8$, requires C, 50 8; H, 6 3, N, 4 2 per cent)

In a similar way, β-DL-phenylalanine benzyl ester (2 8 g) in methylene chloride (100 ml) was condensed with 1,2 3,4-di-*O*-isopropylidene-D-galacturonic acid (3 1 g) in the presence of di*cyclo*hexylcarbodiimide (3 5 g) to yield benzyl *N*-(1,2 3,4-di-*O*-isopropylidene-D-galacturonyl)-β-DL-phenylalanate (0 8 g), m p 115°–116° [from ethyl acetate–light petroleum (b p 60°–80°)], $[\alpha]_D$ −92 8° (*c* 0 88 in chloroform) (found C, 65 7, H, 6 2, N, 3 0 $C_{28}H_{33}NO_8$; requires C, 65 7, H. 6 5, N, 2 7 per cent) Debenzylation afforded *N*-(1,2 3,4-di-*O*-isopropylidene-D-galacturonyl)-β-DL-phenylalanine with m p 211°–215° (from ethyl acetate–light petroleum (b p 60–80°)), and $[\alpha]_D$ − 130 5° (*c*, 1 0 in chloroform) (found C, 59 5, H, 6 6, N, 3 4 $C_{21}H_{27}NO_8$, requires C, 59 8, H, 6 45, N, 3 3 per cent)

The stability of the amide linkage in the two analogues was assessed by determination[5] of the hydrolytically released amino-acid with ninhydrin Aliquots (2 ml) containing *N*-(1,2 3,4-di-*O*-isopropylidene-D-galacturonyl)-glycine (144 μg) in N hydrochloric acid were hydrolysed to extents of 24 5, 42 9, 53 6 and 59 8 per cent after 1, 3, 4 and 6 h at 100° The compound was more unstable in alkali and, after similar treatment with N sodium hydroxide at 100°, the percentage hydrolysis was 52 1 (0 5 h), 69 6 (2 5 h) and 83 7 per cent (3 5 h) By contrast, *N*-(1,2 3,4-di-*O*-isopropylidene-D-galacturonyl)-β-DL-phenylalanine was more unstable in acid than in alkali Thus, aliquots (2 ml) containing amino-acid derivative (1 mg) in 30 per cent aqueous alcoholic 0 5 N hydrochloric acid were hydrolysed to the following extents 10 (1 h), 13 (2 h), 18 (3 h) and 35 per cent (6 h) at 92° compared with 4 (1 h), 11 5 (2 h), 24 per cent (4 h) in 30 per cent aqueous alcoholic 0 5 N sodium hydroxide at the same temperature

Influence of Hydrostatic Pressure on Orientation in Electrophilic Aromatic Substitutions

M G Gonikberg *et al* [1-3] have recently found that at high pressures the attack of phenyl radicals on tertiary butyl benzene yields an appreciably higher proportion of the sterically strained 2-phenyl isomer than it does at atmospheric pressure

We have observed a similar effect in the electrophilic nitration of 1,3-xylene by nitronium ions, NO_2^+ The nitrations were carried out under the same conditions and by the same methods that we had previously used in reaction rate measurements[4] The initial composition of the reaction mixtures, expressed in mole fractions, was nitric acid, 0 618, acetic acid, 0 369, 1,3-xylene, 0 013 We analysed the products by gas chromatography at several stages during the course of each reaction and found that the isomer ratios were independent of the extent of reaction Table 1 lists the results

Table 1 Mole Fractions of Isomers formed in the Nitration of 1,3-Xylene by Nitric Acid in Acetic Acid Solution at 0° C

	Nitro isomer		
Pressure (atm)	2-	4-	5-
1	0 107	0 880	0 013
800	0 150	0 833	0 017
1,200	0 164	0 816	0 020
2,000	0 171	0 829	

It will be seen that between 1 and 2,000 atmospheres the proportion of substitution at the sterically hindered 2-position increased by 60 per cent The change is larger than that observed by Gonikberg[1-3] presumably because in 1,3-xylene there are two adjacent groups tending to obstruct attack on the 2-position Our result supports Gonikberg's general thesis that an increase in pressure tends to favour the formation of sterically compressed isomers

However, some other experiments have shown that the steric factor is not the only important one in nitrations Under the same experimental conditions that applied in the nitration of 1,3-xylene, we found that toluene and chlorobenzene yielded decreasing proportions of the 2-nitro isomers as the pressure was increased The results are given in Table 2

Table 2 MOLE FRACTIONS OF ISOMERS FORMED IN THE NITRATION OF TOLUENE AND CHLOROBENZENE BY NITRIC ACID IN ACETIC ACID SOLUTION AT 0° C

Pressure (atm)	Toluene			Chlorobenzene		
	Nitro isomer			Nitro isomer		
	2-	3-	4-	2-	3-	4-
1	0 560	0 020	0 420	0 247	—	0 753
1,200	0 550	0 022	0 428			
2,000	0 543	0 024	0 433	0 204	—	0 796

Although the shift of isomer ratio in these cases was relatively small, there was a consistent trend with increasing pressure and its direction was the same whether the groups already present on the benzene ring had electron donating (activating) or electron accepting (de-activating) properties

Experiments at atmospheric pressure[5] have established that a change of solvent alters the ratios of isomers formed in the nitration of alkyl benzenes by nitronium salts The effect almost certainly arises from changes of dielectric constant and solvation Presumably similar factors operate when the dielectric properties of the nitrating solution are altered by an applied pressure, and they are supplementary to the simple steric effect Moreover, it is possible that compression may alter the distribution of electrical charge around the benzene rings We hope to distinguish these factors more clearly in future work

BIOCHEMISTRY

Amino-acid Sequences within the Ferrichrome Cyclic Hexapeptides

AN earlier communication[1] concerned with the structures of ferrichrome and ferrichrome *A* left open the particular arrangement of the 3 residues of neutral amino-acids and 3 residues of δ-*N*-hydroxyornithine[2] within the cyclic hexapeptide moiety of the naturally occurring ferric trihydroxamates The peptide portion of ferrichrome contains 3 residues each of glycine and δ-*N*-hydroxyornithine while, in ferrichrome *A*, 2 of the 3 glycine residues are replaced by serine residues In the present report we propose that the sequence for ferrichrome is *cyclo*-triglycyl-tri-δ-*N*-hydroxyornithyl while that for ferrichrome *A* is most probably *cyclo*-diseryl-glycyl-tri-δ-*N*-hydroxyornithyl

Ferrichrome was hydrogenated with Raney nickel in order to eliminate both the iron and the three oxygen atoms of the hydroxamate functions[3] The product was precipitated from methanol–acetone to yield colourless prisms with m p 262°–265° (uncorr , decomp) A synthetic specimen was obtained by the successive addition of three residues of α-*N*-carbo-benzoxy-δ-acetylornithine-*p*-nitrophenyl ester to triglycine ethyl ester, followed by de-blocking and cyclization of the linear hexapeptide This choice of sequence was predicted on the observation that diglycine appears during partial acid hydrolysis of ferrichrome and on the recent discovery by Czech workers[4] that triserine occurs in the related compound albomycin The natural and synthetic products displayed the same m p (decomp) and the same R_F in acidic, neutral and basic solvents Exposure of the two preparations to 12 N hydrochloric acid at 30° for 1 5 days provided an identical array of ninhydrin-positive spots after analysis by paper electrophoresis in 4 per cent formic acid

Ferrichrome *A* was degraded by a bacterium which had been isolated from soil through enrichment culture on the ferrichrome compounds as sole source of carbon and nitrogen The complex pattern of peptides present in the culture medium was separated by Moore-Stein[5] chromatography and selected members were subjected to sequence analysis by use of standard reagents such as fluorodinitrobenzene and hydrazine These investigations revealed the presence of the tripeptide seryl-glycyl-δ-*N*-acylhydroxyornithine A dipeptide, believed to be serylserine, was produced through partial acid hydrolysis of iron-free ferrichrome *A*

In summary, it appears that the cyclic hexapeptide core of the ferrichrome growth factors shares a common component with the albomycin antibiotics, namely, a tripeptide of δ-*N*-hydroxyornithine

This work was supported by the U S Public Health Service (grant No *E*–4156) and the Office of Naval Research (grant No 222–39) The Moore–Stein chromatography was performed through the courtesy of Dr R David Cole

Hydrolysis of Some Antibiotics and of their Decomposition Products in the Presence of Cation Exchange Resins

THE conditions under which some antibiotics are hydrolysed may be important for the isolation and identification of the products of their decomposition since these are used in investigations of the structure of the antibiotics During hydrolysis with mineral acids some moieties, such as carbohydrates, may be destroyed, and much humin may be produced which makes it difficult to isolate the more stable products of decomposition in pure form

A new method of hydrolysis of some antibiotics with the aid of sulphocationic resins of the 'Dowex-50' type is described here By varying the conditions of the experiments (temperature, time, type of resin) different products of hydrolysis may be obtained without their complete degradation and without the production of humins At the same time basic substances can be separated from neutral and acid products The basic substances are adsorbed on the cationic resin while the neutral and acid products are retained in the mother liquor

By gradient elution with various eluants different basic products adsorbed on the ion-exchange resins can be separated The following sulphonic resins were used for hydrolysis 'Dowex-50 × 12' (50–100 and 100–200 mesh)

Table 1 DEGRADATION WITH THE AID OF ION-EXCHANGE RESINS OF VARIOUS ANTIBIOTICS AND OF THE PRODUCTS OF THEIR DECOMPOSITION

Antibiotic	Resin	Time of hydrolysis (h, 105°)	Products of hydrolysis observed	
			Eluate	Mother liquor
Monomycin	*KU*-2	1	Monamine, monomycin, second component	
,,	,,	2	the same	
,,	,,	4	monamine, second component	
,,	,,	48	glucosamine, diaminohexose, streptamine, traces of monamine	
,,	'Dowex 50 × 12' (100–200 mesh)	43	the same	
,,	'*KB*4*P*'2 (carboxylic)	43 43	monomycin, monamine, diaminohexose	
"Second component" after methanolysis of monomycin	'*KU*-2'	1 5	positive reaction with hydrophthalate	
,,		14	diaminohexose	ribose
Neomycin	'*KU*-2'	4 5	neamine, neobiosamine	
,,	,,	48	neamine, diaminohexose	
,,	'*KB*4*P*2'	43	neomycin, neamine, diaminohexose	
Kanamycin	'*KU*-2'	3	kanamycin, products of its partial hydrolysis	
,,	,,	24	two aminoglucoses, streptamine	
Amphomycin	'*KU*-2'	3	mixture of peptides, products of partial hydrolysis	
,,	,,	24	amino-acids, products of total hydrolysis	
Actinoidin	'Dowex 50 × 12' (50–100 mesh)	20		glucose, mannose, acid phenolic component

and '*KU*–2' in hydrogen form The following antibiotics were hydrolysed neomycin, kanamycin, amphomycin, as well as monomycin[1] and actinoidin[2] isolated in our laboratory The products of hydrolysis were identified on circular or descending chromatograms in appropriate systems of solvents[3] For each 100 mg of the substance to be hydrolysed 1·g of the resin and 50–100 volumes of 0 05 N hydrochloric acid were used Solutions of the substances under study were sealed in ampoules together with the resin and kept at 105° C with shaking for various periods of time After hydrolysis the resin was separated from the mother liquor, carefully washed and placed in a column for chromatography The mother liquor was analysed for the presence of neutral (sugars) and acid products

The elution of the basic products adsorbed on the cationic resin was carried out with increasing concentrations of hydrochloric acid (1, 2, 4 N) or ammonia The solvents were evaporated and the dry residues were dissolved in 50 per cent methanol The antibiotics neomycin, kanamycin and monomycin, as well as their nitrogenous decompositon products, are completely adsorbed on the resin and cannot be detected in the mother liquor On the other hand, actinoidin is not adsorbed by this type of resin and remains in the solution, but in the course of hydrolysis the nitrogenous products of decomposition are adsorbed by the resin In the latter case the course of hydrolysis was followed by measuring the decrease with time of the optical density at 280 mμ of the liquid filtered from the resin

The 'second component' of monomycin, consisting of diaminosugar and ribose, was originally obtained by methanolysis of the antibiotic in absolute methanol saturated with 0 5 N hydrochloric acid The hydrolysis of this component was followed by measuring the Bial reaction in the mother liquor and in the eluate from the resin Humins were not observed in the mother liquor or in the eluates

Observations on the hydrolysis of some antibiotics are presented in Table 1 The products of degradation of neomycin and monomycin after hydrolysis on the resin for 4 h are closely related to the products of methanolysis of these antibiotics The only difference is that the 'second component' derived from monomycin and the neobiosamine derived from neomycin possess free glucosidic hydroxyl groups after hydrolysis, whereas these groups are easily methylated during methanolysis When the 'second component' obtained by methanolysis of monomycin is hydrolysed with the aid of a cationic resin, the removal of the methyl group occurs in 1 5 h The complete splitting of this product into ribose and diaminohexose takes place in 12 h When actinoidin is hydrolysed under similar conditions, the mannose and glucose residues in this antibiotic can be detected in the mother liquor This mother liquor also contains an acidic phenolic component absorbing at 280 mμ, which had not hitherto been observed in acid hydrolysates of actinoidin

Purification and Analysis of Human Saliva Lysozyme

JOLLÈS[1,2] has previously demonstrated that lysozymes isolated from different organs of the same animal (dog spleen and kidney; hen egg-white and lung) have qualitatively the same biological activity but differ by their amino-acid compositions and their chromatographic behaviour

This work is part of a comparative study devoted to lysozymes of human origin The purification of human milk lysozyme[3] and the purification and analysis of human placenta lysozyme[4] have already been reported We describe here the purification and the analysis of human female saliva lysozyme

Lysozyme activity was determined by its bacteriolytic action on *Micrococcus lysodeikticus* and expressed as hen's egg-white lysozyme The proteins were titrated with the Folin–Ciocalteu reagent and also expressed as hen's egg white lysozyme after comparison with a standard solution containing lysozyme from Armour (Kankakee, Illinois) The amino-acids have been determined after total hydrolysis (6 N hydrochloric acid, 110°, 24 or 48 h, sealed tube) with a Technicon autoanalyser according to the method of Piez and Morris[5] The cystine and methionine contents have been determined on a performic acid oxidized sample Tryptophan has been determined according to Spies and Chambers[6]

Saliva was collected from women during the day and diluted each evening with water (1 4, v/v) The solution is adjusted to *p*H 4 5 with acetic acid and heated during 2 min at 100° C As with all previously studied lysozymes, saliva lysozyme resists to this treatment, contrary to a great number of other enzymes, and remains in solution Many impurities precipitate and can be eliminated by centrifugation The saliva is then stored at 4° until needed

The purification includes three steps, according to the procedure described by Jollès *et al* [7] (1) Adsorption of the lysozyme on 'Amberlite *CG*–50' buffered with a 0 2 M phosphate buffer of *p*H 6 5 20 ml of 'Amberlite' are added to 1,000 ml of diluted saliva The mixture is stirred overnight The resin is then put into a column and washed with water The lysozyme is eluted with a

0 8 M phosphate buffer of *p*H 6 5 After dialysis, against water at 2° C, a 'primary material' is obtained, its specific activity is 0·3 It should be kept in mind that the specific activity of hen's egg-white lysozyme is 1.

(2) Chromatography of the 'primary material' on carboxymethyl-cellulose (CM-cellulose) The 'primary material' corresponding to 200 ml of undiluted saliva is charged at *p*H 4 5 on a CM-cellulose column (70 × 1 6 cm) equilibrated with a 0 03 M phosphate buffer of *p*H 5 5 Gradient elution is begun after 100 ml by allowing successively a 0 03 M (600 ml), a 0 1 M (600 ml) and a 0 2 M phosphate buffer at *p*H 7 2 to flow into the buffer at *p*H 5 5 in a mixing chamber with a capacity of 250 ml The lysozyme is eluted between the 80th and 140th 10-ml fractions of the third gradient, the active fractions have a specific activity of around 2 5 The purified lysozyme is concentrated by adsorption on a few ml of 'Amberlite *CG*–50' and elution, as described here, it is then dialysed against a 0 2 M phosphate buffer of *p*H 6 98

(3) Ion-exchange chromatography on 'Amberlite *CG*–50' This chromatography is carried out on 16 × 1 1 cm columns of 'Amberlite *CG*–50', Type II, equilibrated with a 0 2 M phosphate buffer of *p*H 6 98

Lysozyme content of saliva In order to avoid some errors which might arise from the presence of activators or inhibitors in the saliva, this content has been determined after obtaining the 'primary material' Human saliva (from women) contains 150–200 μg lysozyme/ml (quantity expressed in hen's egg-white lysozyme)

Chromatography on CM-cellulose The lysozyme was obtained with a yield of 60 per cent and has undergone approximately a 10-fold purification

Ion-exchange chromatography It was carried out as indicated in Fig 1 without any change in the *p*H, the molarity or the temperature of the buffer Saliva lysozyme was eluted after 48 ml with a yield of 90 per cent, the specific activity inside the peak remaining constant (3 ± 0 5) Just before this main peak a very small one is eluted, its specific activity is lower It has not been submitted to amino-acid analyses

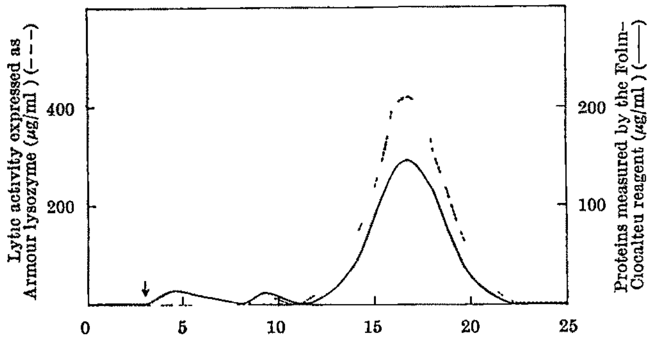

Fig 1 Ion-exchange chromatography on 'Amberlite *CG*-50' of human saliva lysozyme, 0-2 M phosphate buffer of *p*H 6 98

Amino-acid composition Table 1 indicates the amino-acid composition the preferred integer is derived from analyses carried out after 24 or 48 h hydrolysis on samples submitted or not to a performic acid oxidation With three different lots we have obtained the same results

Table 1 AMINO-ACID COMPOSITION OF HUMAN SALIVA LYSOZYME

Amino-acids	*r*	Amino-acids	*r*
Gly	13 ± 1	Ileu	4
Ala	12 ± 1	Phe	2
Ser	6 ± 1	Tyr	5
(Cys-)$_2$	6	Try	5 ± 1
Met	1	Asp	18 ± 1
Thr	6 ± 1	Glu	9 ± 1
Pro	3	Lys	4–5
Val	7	Arg	11 ± 1
Leu	8	His	1

r, Residues/mol

Molecular weight From the amino-acid composition it was possible to calculate a minimum molecular weight of around 14,000 Some experiments made with calibrated 'Cellophane' membranes established that this is the real molecular weight

Conclusion The new lytic enzyme is a lysozyme, as it possesses the principal properties of this group[2,8] it is a basic protein, with a low molecular weight (around 15,000), stable at acid *p*H, unstable at alkaline *p*H, active against suspensions of *M lysodeikticus* It has been obtained in a chromatographically pure state, after an ion-exchange chromatography The specific activity and the amino-acid analyses are constant from one lot to another

From our comparative studies, we can conclude that human placenta lysozyme[4] has the same chromatographic behaviour, the same specific activity and a quite comparable amino-acid composition (established after 18 and 24 h hydrolysis only) as human saliva lysozyme A comparison of the tryptic units will allow us to establish if the two lysozymes are identical or not Preliminary experiments have already shown that human milk contains in fact two lysozymes, one of which seems to be different from the two mentioned here[9]

Citrate as an Intermediary in the Inhibition of Phosphofructokinase in Rat Heart Muscle by Fatty Acids, Ketone Bodies, Pyruvate, Diabetes and Starvation

IN perfused rat heart, glycolysis is accelerated by anoxia and uncouplers of respiratory chain phosphorylation and inhibited by the respiration of fatty acids, ketone bodies and pyruvate[1–4] Measurements of the concentrations of hexose phosphates have led to the suggestion that these agents change the rate of glycolysis by altering the rate of the phosphofructokinase step[1–3] The rates of glycolysis and of the phosphofructokinase reaction are also diminished in hearts from alloxan diabetic or starved rats in which the release of fatty acids from glycerides for oxidation is enhanced[4,5] In extracts of guinea pig heart[6] and of rabbit skeletal muscle[7] the activity of phosphofructokinase is inhibited by increasing concentrations of ATP and stimulated by increasing concentrations of 5′ AMP, cyclic 3′,5′ AMP, ADP and inorganic phosphate These observations suggest that anoxia and uncouplers of respiratory chain phosphorylation increase the rate of the phosphofructokinase reaction in muscle (and hence of glycolysis) by increasing the concentrations of 5′ AMP, ADP and inorganic phosphate and diminishing that of ATP

On the other hand, when phosphofructokinase in rat heart is inhibited by the respiration of fatty acids, ketone bodies and pyruvate or by diabetes or starvation there is no increase in the concentration of ATP and no consistent decrease in that of 5′ AMP, ADP or phosphate This has led to the suggestion[4] that some intermediate in the respiration of fatty acids, ketone bodies and pyruvate might inhibit phosphofructokinase The metabolites which we have considered in this connexion are long-chain fatty acyl coenzyme A, acetyl coenzyme A and the acids of the citrate cycle

The concentration of fatty acyl coenzyme A in perfused rat heart has been assayed as coenzyme A (ref 8) after extraction and separation from the frozen and powdered muscle[9] In diabetes or starvation or after perfusion with 0 75 mM palmitate complexed with 2 per cent bovine plasma albumin the concentration of fatty acyl coenzyme A was increased 40–70 per cent (from control values of 2 4 to 5 0 μmoles/100 g) In hearts perfused with pyruvate (60 mg/100 ml) or DL β hydroxybutyrate (70 mg/100 ml) the concentration of fatty acyl coenzyme A was not increased It seemed unlikely, therefore, that these factors inhibited phosphofructokinase by raising the intracellular concentration of fatty acyl coenzyme A The concentration of acetyl coenzyme A in perfused rat heart was found to be too low for enzymatic assay[10], but acetyl coenzyme A at concentrations between 0 08 and 1 07 mM did not inhibit phosphofructokinase in extracts of rat heart Citrate, on the other hand, in the range of concentrations found in rat heart inhibited phosphofructokinase in extracts of the muscle Moreover, its concentration in perfused heart was increased by all the factors which are thought on the basis of measurements of hexose phosphate concentrations to inhibit the enzyme in the perfused heart These observations, which suggest that the inhibitory effects of fatty acids, ketone bodies, pyruvate, diabetes and starvation on phosphofructokinase in the intact muscle are mediated through an increase in the intracellular concentration of citrate, are briefly summarized

Rat hearts were perfused, frozen and powdered as described elsewhere[1,3] For assay of citrate the frozen powder was extracted with 0 5 M perchloric acid (3 ml /g), neutralized with 60 per cent potassium hydroxide, treated with '*IR* 120' (*H* form) to remove glutathione and neutralized again with 20 per cent potassium hydroxide Citrate was assayed enzymatically by the change in extinction at 340 mμ in a Beckman spectrophotometer on adding 10–20 units[11] of aconitase[12] (purified to the first ethanol precipitation) to a mixture of 0 5 ml muscle extract and 0 7 ml assay medium (70 mM, *tris* hydrochloric acid, 0 7 mM, EDTA, 2 mM, MnSO$_4$, 0 3 mM, NADP, pH 7 4) after removing isocitrate and glucose and fructose 6-phosphates with isocitrate dehydrogenase, glucose 6-phosphate dehydrogenase and phosphoglucoisomerase Citrate was re-assayed in some extracts with citrate lyase[12] (*EC* 4 1 3 6), with essentially similar results The concentration of citrate was assayed in hearts from fed rats perfused for 15 min with medium containing glucose (1 mg/ml) and insulin (0 1 unit/ml) and calculated as μmoles citrate/ml intracellular water The concentration of citrate was increased by starvation and alloxan diabetes from 0 47 ± 0 03 to 0 69 ± 0 08 and 2 38 ± 0 11 respectively, by 0 75 mM palmitate carried by 2 per cent bovine plasma albumin from 0 48 ± 0 08 to 1 64 ± 0 15, by pyruvate (60 mg/100 ml) from 0 67 ± 0 07 to 2 38 ± 0 24, by β-hydroxybutyrate (70 mg/100 ml) from 0 67 ± 0 07 to 1 40 ± 0 16 (mean ± *S E*) for six hearts in each group

For assay of phosphofructokinase in extracts hearts from fed normal rats were perfused anaerobically with glucose-free medium for 15 min (to remove glycogen) and extracted in an all-glass hand-operated Potter–Elvehjem homogenizer with 5 ml assay medium (see later) containing 2 5 mM ATP Phosphofructokinase was assayed in a recording fluorimeter by the disappearance of NADH, the fructose 1 6-diphosphate formed being converted to glycerol 1-phosphate The assay medium was that described by Passonneau and Lowry[7] with 2 5 mM, ATP, 0 05 mM, NADH, 30 μg/ml aldolase and 30 μg/ml glycerol phosphate dehydrogenase (if ammonium sulphate suspensions of enzymes are used they should be limited in volume to a total of 0 6 ml /100 ml as ammonium sulphate can block citrate inhibition) Rotenone (0 7 μg/ml) was added to inhibit NADH oxidase activity After steady-state conditions were attained with 10–20 μl muscle extract and 3 ml assay medium, the reaction was started by addition of 20 μl of 0 15 mM (glucose + fructose 6-phosphates) containing 10 μg/ml phosphoglucose isomerase The effect of various substances on the activity of phosphofructokinase was ascertained by the change in rate on their addition to the complete reaction mixture Control experiments showed that substances which altered the rate of conversion of fructose 6-phosphate to glycerolphosphate did not change the rate of conversion of fructose 1 6 diphosphate (7 μM), that is, that their influence was on phosphofructokinase

The activity of phosphofructokinase in extracts of rat heart was 140 μmoles fructose 1 6 diphosphate formed/g of wet heart/h (23 observations) In each of 10 experiments citrate (mM) reduced the rate to an average of 23 per cent of the control Definite inhibition (80 per cent control) was seen with as little as 0 2 mM citrate and the effect increased between 0 2 and 1 mM Citrate inhibition was not influenced by an equimolar amount of Mg^{2+} No inhibition was seen with (mM) *cis*-aconitate, L_s isocitrate, α-oxoglutarate, succinate, fumarate L-malate, tricarballylic acid, acetyl coenzyme A or coenzyme A The activity of phosphofructokinase was enhanced by 5′ AMP (0 17 mM), cyclic 3′,5′ AMP (0 17 mM), ADP (0 5 mM), inorganic phosphate (4 or 8 mM) and arsenate (8 mM), both in the presence and absence of mM citrate Inorganic phosphate, for example, increased the rate ten-fold at 8 mM Rat heart muscle phosphofructokinase is thus activated by those substances which activate phosphofructokinase from guinea pig heart or rabbit skeletal muscle[6,7] It is also inhibited by citrate Inhibition of brain phosphofructokinase by citrate has been observed by Passonneau and Lowry (personal communication)

These observations suggest that respiratory substrates and diabetes or starvation inhibit phosphofructokinase through an increase in the intracellular concentration of citrate The latter may be due to increased synthesis of citrate through the provision of additional acetyl CoA Other possibilities are alterations in mitochondrial permeability to citrate or in the utilization of citrate either in mitochondria or cell sap

We thank Dr J B Chappell for advice and assistance with the fluorimetric assay of phosphofructokinase, Sir Rudolph Peters, for gifts of tricarboxylic acids, and the British Diabetic Association and British Insulin Manufacturers for financial support

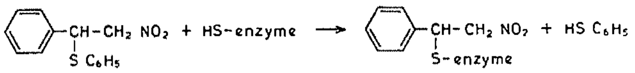
Antifungal Activity of Some 2-Nitro-1-phenyl-1-phenylthioalkanes

In view of the publication by Wain *et al* [1] on the fungicidal properties of some thiocarbamoylthionitroparaffins, we wish to describe the antifungal properties of some 2-nitro-1-phenyl-1-phenylthioalkanes and related compounds

The antifungal activity of αβ-unsaturated carbonyl compounds[2,3] is believed to be due to their ability to combine chemically with the thiol group of many enzymes and coenzymes, thereby causing their deactivation, and it seems likely that the fungitoxicity of β-nitrostyrenes[4–6] arises for similar reasons This is supported by the fact that those compounds possessing the double-bond most reactive towards nucleophilic reagents (for example, thiols) are the most powerful antifungal agents, namely, the β-nitrostyrenes[3,7,8] (Table 1) The compounds obtained by adding benzenethiols to αβ-unsaturated carbonyl compounds and β-nitrostyrenes might therefore be expected to have markedly diminished biological activity, Table 1 reveals that this is not necessarily so Substantially inactive thiol-addition products (type *B*) are apparently obtained only from compounds of type *A* possessing high antifungal activity and highly reactive double bonds (for example, compounds 2, 4, 7 and 9)

In view of this, and the fact that the parent sulphide, 1-phenyl-1-phenylthioethane, is inactive against all four test fungi at 1,000 p p m , it is tempting to suggest that the fungitoxicity of the 2-nitro-1-phenyl-1-phenylthioalkanes may be due to their reacting with the thiol groups of enzymes through exchange reactions



Such exchanges are less likely to occur with the compounds of type B in which the benzenethiol has been added to a highly reactive double-bond (compounds 2, 4, 7 and 9) In these cases, low fungitoxicity would be expected

The present hypothesis also suggests that 2-nitro-1-phenyl-1-phenyl-thioalkanes containing electron-attracting groups attached to the phenylthio moiety should exhibit the greatest fungitoxicity, as the foregoing exchange reaction will be facilitated This is supported by the biological results in Table 2, where compound 15 contains a 4-nitro-group The reverse effect is demonstrated by compound 17, which contains the electron-repelling methoxyl group

Table 2 EFFECT OF SUBSTITUENTS ON THE ANTIFUNGAL ACTIVITY OF SOME 2-NITRO-1-PHENYL-1-PHENYLTHIOETHANES

Saligenin Cyclic Methyl Phosphate and its Thiono Analogue: New Insecticides related to the Active Metabolite of Tri-o-cresyl Phosphate

SALIGENIN cyclic phosphate was discovered as the active metabolite of tri-*o*-cresyl phosphate (TOCP) (ref 1 and 2) Analogous cyclic phosphorus esters were synthetically prepared for examination of their chemical properties[3,4] and biological activities[5,6] The biological activity is not always coincidental with the chemical reactivity and appears to be influenced by the size of a substituent on phosphorus being outside the hetero-ring of the cyclic esters The TOCP-metabolite causes ataxia in hens but has no insecticidal activity, while its analogous cyclic phosphates carrying a small alkyl group appear to have insecticidal activity. The following two esters are new promising insecticides in this unique series.

2-Methoxy-4*H*-1,3,2-benzodioxaphosphoran-2-one (salioxon) was prepared according to a described procedure[3] from saligenin and methyl phosphorodichloridate by the action of tertiary amine. Pyridine was better than triethylamine as the base. The product was a colourless oil, b.p. 110°–112° C (0.05 mm mercury), $n_D^{25°} = 1.5155$. Its thiono analogue (salithion) was not obtained in good yield by a similar procedure, but was by more drastic condition such as heating (80°–90°) the mixture of saligenin and methyl phosphorodichloridothionate in toluene for 15–20 h in the presence of potassium carbonate and copper powder. The thiono analogue consists of colourless needles (from methanol), m.p. 51°–53° C. Cyclic structure of these compounds was supported by infra-red-spectra, aminoantipyrine test[3] and determination of molecular weight.

Parathion			5 (ref. 7)	0.04
Malathion			347 (ref. 7)	0.6

* Oral administration with addition of emulsifier, mg/kg, 24 h.
† Topical application of acetone solution, γ/female, 24 h.

These methyl esters have strong insecticidal activity comparable with parathion and less toxicity to mammals than the latter as shown in Table 1. They are also effective with some other insects such as the American cockroach, rice stem-borer and green rice leafhopper[7]. Another outstanding character of salioxon is its extremely rapid insecticidal action. It is interesting to note that these insecticidal cyclic phosphorus esters do not have any strong acidic group such as parathion, etc., have.

Analogous esters having a bulky substituent such as aryl group or big alkyl group are not insecticidal. This appears to be due to the differences in affinity for insect enzymes and also in penetration. Non-insecticidal phenyl derivative (R = OPh, X = O) is a strong inhibitor for housefly trunk aliesterase, but not for fly head cholinesterase. Another non-insecticidal phenylphosphonate (R = Ph, X = O) is a strong inhibitor of both enzymes *in vitro* but not *in vivo*. Salioxon inhibited both enzymes *in vivo* as well as *in vitro*.

Relationship between Consistency of Wheat Grain and Flour Diastatic Activity

THERE are annually harvested in Australia more than 100 varieties of wheat, one of the chief reasons for this large number lying in the complexity of soil-type and climate encountered throughout the wheat-belt. It will be appreciated that a considerable diversity of quality types are represented by these varieties and in 1956 a phenomenon referred to as 'over-stability', characteristic of certain extremely vitreous material, received much attention. Flours obtained from these varieties were found to contain a high percentage of damaged starch, arising out of the increased roll-pressure it was necessary to exert on the grain in order to obtain a satisfactory flour yield. Consequently the diastatic activity of these flours was considerably augmented, and the increased dextrinization associated with this high diastatic activity imparted stickiness to the fermenting dough, the resultant loaves being dense, of low volume and poor, waxy texture. In order to ascertain which of the varieties being grown possessed this characteristic and were thus unsuitable for cultivation, a great number of varieties were tested for grain consistency and diastatic activity, and the relationship revealed between these two characteristics forms the subject of this communication.

Flour of each variety was obtained by milling 1 kg of tempered wheat in a Buhler automatic laboratory mill. Flour diastatic activity was measured by a modification of the Blish and Sandstedt procedure[1]. Grain consistency was measured by a particle size index test perfected by Symes[2] and since improved by the introduction of a *Ro*-tap sieve shaker. Ten grammes of grain are ground in a Labconco mill set at its finest setting, and the meal sieved

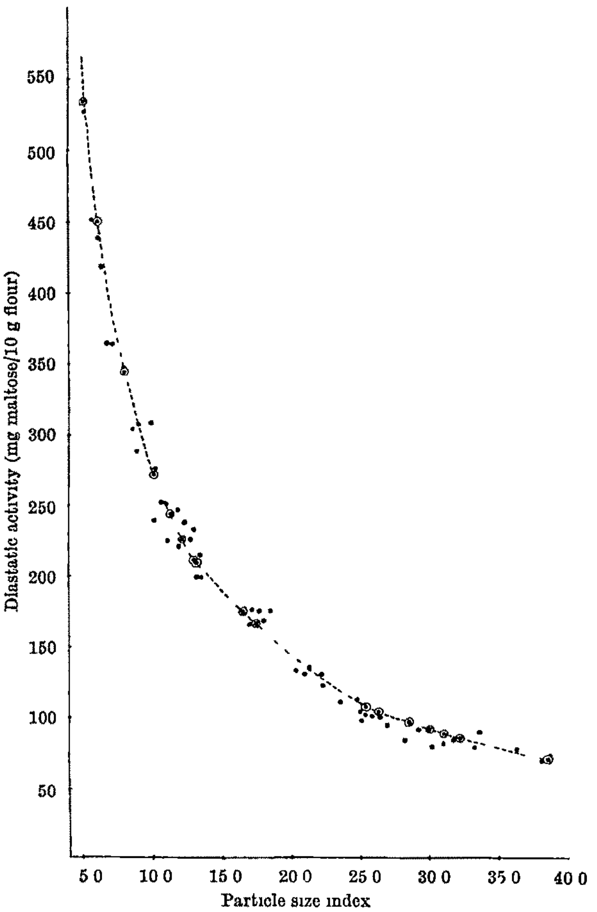

Fig. 1. Relationship between particle size index and flour diastatic activity. γ = 0.992, log Y = 3.441 − 1.004 log X. ○, Predicted flour diastatic activity; ●, observed flour diastatic activity.

Table 1 RELATIONSHIP BETWEEN OBSERVED FLOUR DIASTATIC ACTIVITY AND FLOUR DIASTATIC ACTIVITY PREDICTED FROM A KNOWLEDGE OF GRAIN CONSISTENCY, AS MEASURED BY PARTICLE SIZE INDEX SYSTEM

for 10 min on a 200-mesh wire sieve, the percentage of throughs being recorded as the particle size index *Durum* wheats have an index of 5, while a figure of 40 has been recorded for certain soft biscuit-type varieties

A close logarithmic relationship was found to exist between flour diastatic activity and grain consistency as measured by the particle size index system (Fig 1) By means of this relationship it was possible to predict the flour diastatic activity with some degree of accuracy from a knowledge of the particle size index of the grain (Table 1) From the range of varieties which were classified in this way, 12 varieties, chosen to cover the full range of diastatic activity encountered, were grown for 2 seasons in a series of 10 replicated trials throughout the Australian wheat-belt, in order to test the effect of environmental fluctuations on the classification Preliminary results from these trials have indicated that the logarithmic relationship referred to here is maintained under a variety of edaphic and climatic conditions

Effect of Vitamin B_6 and its Analogues on the Swelling of Rat Liver Mitochondria

IT has been observed[1,2] that substances like thyroxine, Ca^{++}, orthophosphate, induce swelling in rat liver mitochondria when suspended in a medium containing 0 3 M sucrose, and 0 02 M *tris*(hydroxymethyl)aminomethane, at *p*H 7 4 That the swelling of mitochondria is dependent on the respiratory chain is shown by the fact that 2,4-dinitrophenol, which is an uncoupler of oxidative phosphorylation, is a strong inhibitor of mitochondrial swelling[1]. The swelling of mitochondria is associated with the active water uptake, which was first pointed out by Raaflaub[3] The active water uptake is also inhibited by adenine triphosphate[4] Other substances like spermine, spermidine, and related polyamine also inhibit swelling[5] It has also been observed that many antihistamine drugs inhibit mitochondrial swelling[6] where permeability change has been suggested It is known that pyridoxal phosphate intensifies the uptake of amino-acids by Ehrlich ascites tumour cells[7] with the concomitant uptake of water A study of the effect of pyridoxal phosphate and other analogues of vitamin B_6 on the active water uptake by rat liver mitochondria will be of some interest

In the present investigation the rat liver mitochondria was isolated by usual methods, and swelling was studied in a medium containing 0 3 M sucrose and 0 02 M *tris*-(hydroxymethyl)aminomethane at *p*H 7 4 by observing the optical density at 520 mμ according to the method[8] published previously The results are shown in Table 1 Of all the various analogues of vitamin B_6 tested, pyridoxal phosphate and 4-deoxypyridoxine inhibit the swelling to the extent of 32 per cent and 75 per cent respectively when present in 2 mM-levels The rest of the compounds are inactive When 4-deoxypyridoxine and pyridoxal phosphate are present together at 1 mM-level, they prevent swelling completely These two compounds together cannot prevent the swelling of rat liver mitochondria caused by thyroxine When other analogues of vitamin B_6 are present along with 4-deoxypyridoxine they do not show any synergistic effect The inhibition of mitochondrial swelling by 4-deoxypyridoxine has similarity to the action of 2,4-dinitrophenol in that it releases the adenosine triphosphatase activity of the mitochondria to about four-fold that of the blank when present in equimolecular level, but on the contrary when 4-deoxypyridoxine and pyridoxal phosphate are present together it is inactive in releasing the adenosine triphosphatase activity *in vitro* of the mitochondria The other compounds are inactive in releasing the adenosine triphosphatase from rat liver mitochondria

Table 1 SWELLING OF RAT LIVER MITOCHONDRIA *in vitro* IN PRESENCE OF VITAMIN B_6 ANALOGUES THE SWELLING OF MITOCHONDRIA IN 0 3 M SUCROSE 0 02 M *tris* MEDIUM AT 15 MIN IS TAKEN AS 100

PHYSIOLOGY

Relationship between Venous Pressure and Cortical Blood Flow

IN man, acute occlusion of the superior vena cava results in complete obstruction to cerebral venous drainage, with gross changes in the electroencephalogram In the dog, however, complete constriction of the superior vena cava results in a rise in cerebral venous pressure, but no significant changes in the EEG[1] (Fig 1) Venous pressure is compounded of a number of variables[2] and a number of pressure-flow relations have been demonstrated in distensible vascular beds[3]

A veni-vasomotor reflex has been postulated for the finger[4] A fall in flow was observed following distension of the venous bed A similar mechanism may result in cerebral ischæmia following increases in intracranial venous pressure with coughing and straining It is, however, more probable that an alternative mechanism is present tending to stabilize cerebral blood flow despite fluctuations in venous pressure This communication supports this possibility

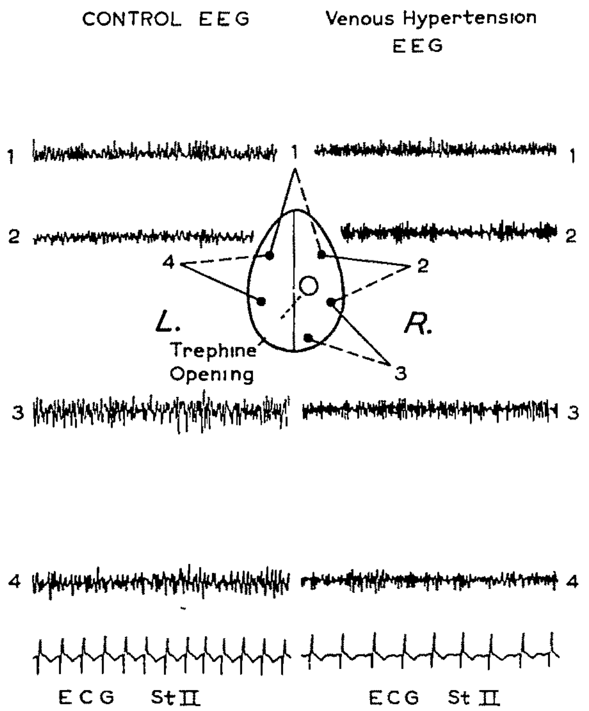

Fig. 1. The EEG before and after venous obstruction. There is no significant difference in the recordings. There was a slowing of the heart rate in this instance after constriction of the superior vena cava.

Tables 1 and 2 show the overall experimental results. S.V.C. + indicates constriction of the superior vena cava; B.P., blood pressure mm mercury; V.P., sagittal sinus venous pressure cm water; Art. pCO_2, arterial carbon dioxide tension, mm mercury; C.B.F., cortical blood flow, ml./gm/min.; C.B.F.″, cortical blood flow normalized to a pCO_2 of 40 mm mercury.

Cortical blood flow (ml./g/min.) was measured in seven dogs with the krypton-85 clearance method of Lassen and Ingvar[5]. Anæsthesia was induced with thiopentone and maintained with nitrous oxide. Intermittent suxamethonium was administered to allow controlled ventilation. Arterial blood pressure was measured (mm mercury) and samples were obtained from a femoral artery cannula. Venous pressure (cm water) was measured from a cannula mounted in the sagittal sinus. Changes in venous pressure were induced by constriction of the superior vena cava exposed by thoracotomy. Arterial pCO_2 was determined using a micro-Astrup apparatus[6] and maintained within narrow limits in each dog by adjusting the stroke volume of the Starling respiratory pump. EEG activity was recorded on an Offner 8-channel *T.D.* electroencephalogram using stainless steel electrodes in bifrontal, fronto-temporal and fronto-occipital positions.

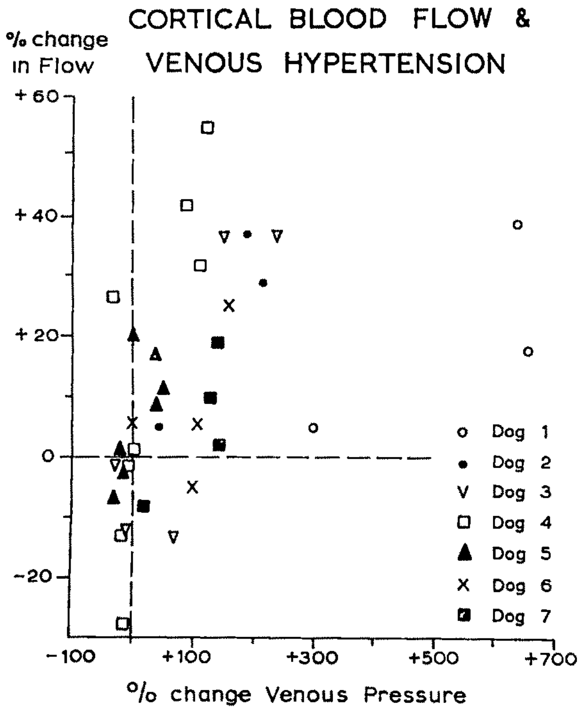

Fig. 2. Illustrates the relationship between the change in flow as a percentage of the initial controls in each dog and the change in venous pressure as a percentage of the initial controls.

After control measurements in three animals, progressive partial constriction of the superior vena cava was applied (dogs 1, 2 and 3). In one animal measurements were made during complete occlusion of the superior vena cava for 42 min and also following release of the constriction (dog 5). A further reduction in cerebral venous return was effected in two dogs by an additional ligation of the vena azygos (dogs 6 and 7). In one animal a closed intracranial system was simulated by sealing the trephine hole and plastic membrane[7] with methyl-methacrylate (dog 4).

The results are expressed in Tables 1 and 2. The control cortical blood flow values show a considerable variation between animals. This is probably attributable to the range in the control arterial pCO_2 levels and the considerable operative trauma required for the preparation. However, in each animal there was an increase in cortical blood flow after venous obstruction. In dog 7, after vena azygos ligation a fall in cortical blood flow occurred, together with a fall in systemic blood pressure and a much greater increment in venous pressure. A smaller increment in flow occurred in dog 6, with combined superior vena cava and vena azygos occlusion compared with the increase in flow in the other animals.

A graphic representation of the relationship between the percentage change in cortical blood flow—adjusted to an arterial pCO of 40 mm mercury—and the percentage change in venous pressure is shown in Fig 2 No simple relationship is evident However, the majority of flow results are within ± 15 per cent of the control values A coefficient of variation of 17 per cent in the mean estimations of several dogs in cortical blood flow has been reported using the krypton-85 technique at a $p\mathrm{CO}_2$ of 40 mm mercury[7] The change in cortical flow persists if venous hypertension is maintained for long periods, but there may be an upper limit of venous pressure after which a fall in flow occurs (dog 7) If a closed intracranial system is reconstituted the response to venous hypertension is unchanged (dog 4) In this animal, however, some loss of cerebro-spinal fluid had occurred prior to the fashioning of the acrylic window The consistent increase in cortical flow in every animal following constriction of the superior vena cava is at variance with reports on finger plethysmography and alterations in venous pressure[4] In this latter investigation, changes in venous pressure were induced by altering tissue tension The influence of tissue tension—cerebro-spinal fluid pressure in this instance—cannot be assessed in those animals using the standard krypton-85 technique[3,7-9] Excision of the dura and replacement with a plastic membrane allow a commensurate loss of cerebro-spinal fluid following alterations in blood flow and venous pressure The preliminary findings after closing the dural window in dog 6 suggest that moderate changes in cerebro-spinal fluid pressure may not alter the response to venous obstruction A provisional conclusion that there is a homeostatic mechanism stabilizing cerebral blood flow despite large fluctuations in venous pressure seems justifiable at this stage

We thank Prof W A Mackey and Sir Charles Illingworth for providing facilities The work was supported in part by a Medical Research Council grant to Prof Mackey and carried out at the Wellcome Research Laboratories, University of Glasgow

Active Transport and Transfer of Energy

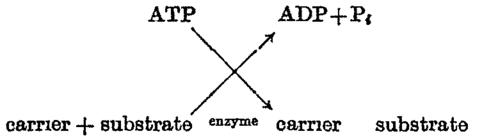
THE transport of ions and molecules across the cell membrane against a concentration gradient is usually defined by the term 'active transport' The word 'active' conveys the idea of active participation of the cells in these transport processes, the energy required being supplied by the metabolic processes within the cells

Certain important features of these processes are: (1) the rate of transport is not a linear function of the difference of concentrations on the two sides of the cell membrane, (2) competition among substances having similar configurations; (3) inhibition by enzyme inhibitors; (4) the temperature coefficients are often of the same order as those of enzyme reactions; (5) the rate of transport may be different even for optical isomers

The mechanisms which have been suggested to explain the active transport processes can be classified into three groups (1) Fixed carrier transport[1]. in this mechanism the carriers present on the cell membrane combine with the molecules or ions on one side of the membrane, then move to the other side and release them there (2) Mobile carrier transport[2,3] in this process the molecules or ions combine with mobile carriers on one side of the membrane, move to the other side and get released there (3) (*a*) Complex formation[4] with macromolecules such as proteins by chelation or electrostatic forces, (*b*) adsorption on colloidal particles

Since active transport processes include the movement of a wide variety of substances under different conditions, it is not unlikely that all these three mechanisms either separately or together are operating in different cases

The active transport processes usually require expenditure of energy The way this energy is utilized depends on the nature of the mechanism involved in any particular process The energy transfers in the two carrier transports are basically the same and are similar to those involved in other synthetic reactions within the cell.



The carriers in the mobile transport processes may be the common metabolites of the cell Due to the anisotropic distribution of enzymes and other reacting constituents on the two sides of the cell membrane, the combination with a metabolite (mobile carrier) on one side and its release on the other side may be more accelerated than the reverse process

The utilization of energy in the active transport processes operated by the mechanism of complex formation with a protein molecule or any other macromolecule may take place in the following ways

(1) Since the anabolism and catabolism of the protein molecules are under the dynamic control of the metabolic processes, the deficiency in the energy-producing processes will affect the steady state of the process

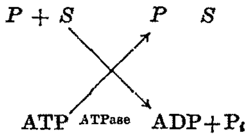
$P + S \rightleftharpoons P\quad S$, where P is a protein molecule and S is a substrate and hence will affect the active transport of S

(2) The enzyme ATPase is necessary for the breakdown of ATP to ADP:

$$\mathrm{ATP}\xrightarrow{\overbrace{[\mathrm{ATPase}]}^{\mathrm{Mg}^{++},\ \mathrm{Na}^{+},\ \mathrm{K}^{+}}}\mathrm{ADP}+\mathrm{P}_i$$

The rate of this reaction depends on the concentration of the complex of ATPase with Mg^{++}, Na^{+} and K^{+} which in turn depends on the concentration of these ions If they are below certain optimum concentrations, variations in their concentrations will greatly affect the rate of utilization of ATP.

(3) The energy may also be utilized by the following coupling processes



Two other phenomena are associated with active transport processes One is the resting potential of the cell and the other is transmission by nerves In the resting state the ions are partly in the bound form and partly in the free state Due to these complex formations there are unequal distributions of the ions on the two sides of the cell membrane The protein and other macromolecules are continuously undergoing repeated catabolism and anabolism At the time of catabolism of the macromolecules, the ions are liberated in the free state and these free ions tend to move to the other side of the cell membrane to attain equilibrium state. However, before the ions can attain the equilibrium state, the macromolecules are again synthesized and start forming complexes with the ions, which, therefore, move across the cell membrane in the reverse direction against the concentration gradient. Thus there is always an unequal distribution of certain ions and hence a potential difference between the two sides of the cell membrane.

Acetylcholine is, in the resting condition, in an inactive and bound form. Its release from the bound state and hydrolysis to choline are intimately connected with the transmission along nerves. The initiator in this process is either a configurational change in the protein molecule binding acetylcholine or liberation of free potassium ions from the bound state. The free potassium ions then accelerate the following process:

$$\text{acetylcholine}\quad\text{protein} \xrightleftharpoons{K^+} \text{acetylcholine} + \text{protein}$$

Acetylcholine esterase is present in conductive tissues throughout the whole animal kingdom. The most important feature of acetylcholine esterase is the high speed at which this enzyme can hydrolyse acetylcholine. The choline molecules formed cross the cell membrane and displace some of the sodium ions from the bound state. The free sodium ions enter the cell and cause liberation of some of the potassium ions from the bound state. The free potassium ions from inside the cell start moving to the outside medium. Also the increased concentration of free potassium ions accelerates the resynthesis of acetylcholine:

$$\text{choline} + \text{acetate} \xrightarrow[\substack{\text{choline acetylase}\\ + \text{ATP}}]{K^+} \text{acetylcholine}$$

Then the reverse processes start, choline coming in, sodium ions going out and potassium ions coming back inside the cell. The incoming and outgoing processes of sodium and potassium ions ultimately lead to the transport of bioelectric potential. There are two different types of movement of sodium and potassium ions, one associated with normal metabolic processes and the other with transmission by nerves. The rapid hydrolysis of acetylcholine by acetylcholine esterase in transmission by nerves makes the movement of sodium and potassium ions associated with this process much faster than that associated with normal metabolic processes. This enables the two processes to become distinct from each other and leads to the propagation of bioelectric potential associated with transmission by nerves.

Anorexia produced by Direct-current Blockade of the Vagus Nerve

ACCORDING to a hypothesis presented in a previous communication[1] a tonic information from hepatic glucoreceptors might be stimulating the lateral hypothalamic 'feeding centre'. The reduction of this excitatory input by an increase of intracellular glucose (or some related metabolite) in the hepatic cells would inhibit intake of food.

As the vagus nerves are responsible for substantial innervation to the liver[2] it was thought that these nerves might be the main pathways for the afferent discharges of these hepatic glucoreceptors. Therefore, the blockade of one or both vagus nerves would represent an important reduction in the excitatory input to the 'feeding centre' and this would induce inhibition of intake of food. This would correspond to an increase of intracellular glucose in the liver such as is produced by intraperitoneal glucose injections or by injections of adrenaline[1,3].

A total of 45 experiments were performed on 8 adult cats with chronically implanted electrodes in one or both vagus nerves. In one of the cats, electrodes were also implanted in the glossopharyngeal. The animals were conditioned to reach for food when four 1/sec flashes were applied. In the experimental trials, direct current of 0·6–1·5 m.amp. was applied through the implanted electrodes after the second flash. The current intensities were previously confirmed to block nerve conduction in the vagus in acute experiments. The animals were tested after a 24-h fasting period.

In several control experiments it was observed that the cats ate eagerly all the meat portions (twenty) given to them. When direct current was applied to either or both vagus nerves after the second flash, the cats did not reach for the food but remained in the resting position. After the cessation of the current, the animals did not eat for a period of 5–10 min even if the flashes were repeated. When direct current was applied to the glossopharyngeal instead of the vagus, the animals' feeding behaviour was not modified.

The foregoing results establish that a direct current of sufficient intensity to block nerve impulses is capable of producing immediate anorexia when applied to the vagus but not when applied to the glossopharyngeal. This does not provide any direct evidence of the existence of hepatic glucoreceptors, but does indicate that some nervous information related to food-intake regulation is coursing the vagus, which agrees with the aforementioned hypothesis.

It was shown by one of us in another communication[4] that, if the direct current applied to the vagus is prolonged sufficiently, the animals enter into natural electroencephalographic sleep, indicating the close interrelationship existing between the regulatory-mechanisms of appetite and sleep, as pointed out by Soulairac[5].

PHARMACOLOGY

Anti-anaphylactic Action of Acetylsalicylate in Guinea Pig Lung

HISTAMINE, plasma kinins and slow-reacting substance (SRS-A) are released or produced in anaphylaxis[1-3]. In the guinea pig, intravenous injection of each of these substances causes bronchoconstriction[4,5]. The bronchoconstriction induced by kinins or SRS-A is readily prevented by acetylsalicylic acid or its salts (acetylsalicylate), but not by mepyramine, whereas that induced by histamine is prevented by mepyramine, but not by acetylsalicylate[4-7]. These facts suggest that both drugs together might pro-

A, Sodium acetylsalicylate, *E*, egg albumen, *M*, mepyramine maleate, in parentheses, doses in mg/kg intravenously, acetylsalicylate being expressed as weight of acid and mepyramine, of base Acetylsalicylate was given 15 min and mepyramine 10 min before egg albumen

tect guinea pigs against anaphylactic bronchoconstriction and that each drug separately might have a partial protective action Although mepyramine has been shown to exert some protection[6,8], previous attempts have failed to show that acetylsalicylate[6] or salicylate[9,10] were effective Stresemann[11] has recently reported that amidopyrine, phenazone and phenylbutazone partially protected guinea pigs against an aerosol of antigen; but large doses of drug were needed and he considered the effect non-specific The present communication describes a fuller investigation of the action of acetylsalicylate against anaphylactic bronchoconstriction in the guinea pig

Konzett-Rossler[12] preparations of guinea pigs sensitized to egg albumen were set up as previously described[4], to record pulmonary resistance to inflation, except that the side vent of the recording apparatus was automatically clamped for 7–9 sec during each ½ min to inflate the lungs more forcibly All treatments were intravenous and all animals received egg albumen, 2 mg/kg Some animals were also given mepyramine maleate, 2 or 5 mg base/kg, 10 min before egg albumen, some animals were treated with sodium acetylsalicylate 1 or 8 mg acid/kg, 15 min before egg albumen, some animals received both drugs From the record of resistance to pulmonary inflation obtained from each animal, the maximal excursion within 2 min of injecting antigen was measured

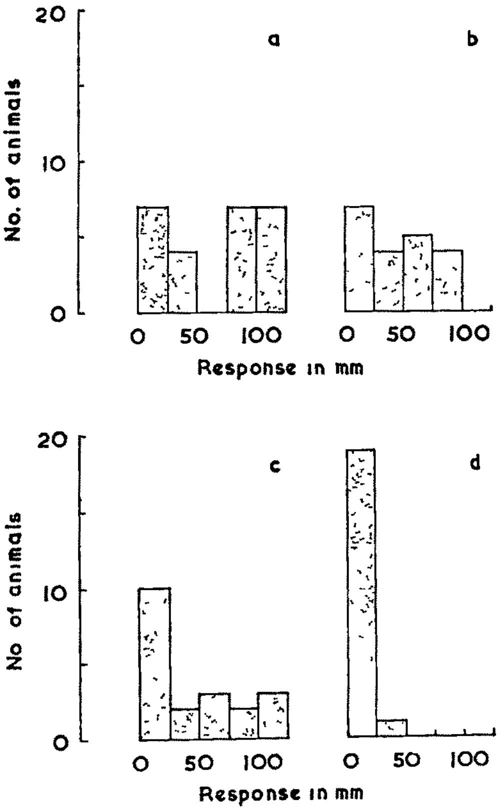

Fig 1 Frequency distribution of the size of the bronchoconstrictor response to antigen in the guinea pig after (*a*) no drug, (*b*) mepyramine, 2 mg/kg, (*c*) acetylsalicylate, 8 mg/kg, (*d*) acetylsalicylate, 8 mg/kg + mepyramine, 2 mg/kg Results from Exp 3 of Table 1

Table 1 summarizes the results of four experiments in a total of 314 guinea pigs The first experiment confirmed that mepyramine reduces anaphylactic bronchoconstriction The second experiment showed that acetylsalicylate also was active and the third that both drugs together were significantly more effective than either drug alone In the fourth experiment, in mepyramine-treated animals, a relationship was shown between the dose of acetylsalicylate and the extent to which bronchoconstriction was reduced

Fig 1 expresses the frequency-distribution of the size of response to antigen among the guinea pigs in experiment 3 of Table 1 It shows that, after either mepyramine or acetylsalicylate alone, anaphylactic bronchoconstriction was slight in some animals and intense in others, whereas after both drugs together it was always slight This finding suggests that those animals which were not protected by mepyramine alone would have been protected by acetylsalicylate and vice versa The previous attempt[6] to show the protective action of acetylsalicylate in anaphylaxis may therefore have failed because the guinea pigs used happened to have been almost completely protected by mepyramine In the present experiments, many more animals were used, among which an appreciable number were resistant to mepyramine

In the foregoing experiments, the possibility that acetylsalicylate may have acted by inhibiting release of histamine can be dismissed, because this requires a relatively high concentration of drug[13] and because it would not explain the synergism of acetylsalicylate with mepyramine, which is a much more potent inhibitor of histamine liberation in guinea pig lung[14] The possibility that acetylsalicylate may have acted by inhibiting formation of kinins and/or SRS-A cannot be dismissed, but, at the doses effective against anaphylactic bronchoconstriction, such an action has not been demonstrated in the guinea pig *in vivo* Acetylsalicylate itself constricts rather than relaxes guinea pig bronchioles It does not antagonize the bronchoconstrictor action of histamine, acetylcholine or 5-hydroxytryptamine, but it does antagonize that of kinins[4,6,7] and of SRS-A[5], probably competing with kinins for receptor sites on bronchioles[15] In view of these facts, the present findings indicate that kinins and/or SRS-A contribute to anaphylactic bronchoconstriction in the guinea pig and that acetylsalicylate lessens this effect by antagonizing one or both of these substances at their receptors in bronchial muscle If the anti-asthmatic action of acetylsalicylic acid in man, recently demonstrated by Stresemann[11], resembles in mechanism its anti-anaphylactic action in guinea pig lung, this drug might be expected to be more effective in bronchial asthma if given together with an anti-histamine

Effects of α-Methyl DOPA and DOPA on the Amphetamine Excitatory Response in Reserpinized Rats

IN the course of investigations into the actions of certain anti-depressant compounds on the excitatory response to amphetamine in rats[1], we have found that L-α-methyl-3,4-dihydroxyphenylalanine (α-Me DOPA) antagonizes the reserpine-induced modifications to the amphetamine response, but that the observed effects of this interaction are completely different if the α-Me DOPA is given after, rather than before, the reserpine

The excitatory response of male albino rats (Tuck Wistar strain), 160–240 g, to *dl*-amphetamine sulphate 5 mg/kg (intraperitoneal) was scored on the following arbitrary scale: 0, rat asleep, 1, alert but not moving, 2, moving around the cage, 3, stereotyped sniffing at bars, 4, licking bars, 5, 'mock' biting (momentarily touching bars with teeth), 6, gnawing bars Half values were scored for appropriate responses The individual scores for each of four rats in a group were noted and summed every half-hour (maximum score = 24) for 5–6 h after the amphetamine injection The scoring was performed by an operator who did not know what treatment the animals had received

Amphetamine in the dose used caused a moderate excitatory response, with all rats sniffing, rarely licking and never biting, the effect lasted 4–5 h (Fig 1) Treatment of the rats with α-Me DOPA 400 mg/kg (intraperitoneal) 2–3 h before the amphetamine reduced its response slightly, if given 18 h before amphetamine, α-Me DOPA did not modify the response at all Reserpine 2 5 mg/kg, injected intraperitoneally 18 h previously, markedly accentuated the amphetamine response both in degree and rate of onset, but reduced it in duration When the two treatments were given to the same rats, however, two quite different responses to amphetamine could be obtained, depending on the order of injection of the reserpine and α-Me DOPA

(1) If α-Me DOPA was given just before reserpine (that is, at 18 5 and 18 h respectively before amphetamine), the amphetamine response resembled that in untreated animals—that is, the modifications to the response induced by reserpine were abolished by α-Me DOPA

(2) If α-Me DOPA was injected 2 h before amphetamine into rats which had received reserpine 16 h earlier, all signs of excitation were abolished The rats sat immobile except for occasional stretching motions, and made no stereotyped sniffing or biting movements This blocking effect of reserpine and α-Me DOPA was not seen in rats treated with the mono-amine oxidase inhibitors nialamide 100 mg/kg or tranylcypromine sulphate 5 mg/kg 1 5–9 h after reserpine

The blockade of the amphetamine response by reserpine and α-Me DOPA could be 'reversed' by a subsequent subcutaneous injection of DL-DOPA 20–50 mg/kg given 0 5–1 5 h after amphetamine (Fig 2) The consequent excitatory response was indeed often greater than that to amphetamine after reserpine; the rats would spar and fight, or bite the bars of the cage strongly and incessantly This 'reactivation' effect lasted about 2 5 h, ending abruptly 5-Hydroxytryptophan 50 mg/kg or dopamine 100 mg/kg did not induce this effect Injection of DOPA to rats given reserpine and α-Me DOPA only, without amphetamine, caused some increased alertness and sensitivity to noise, but little motility and no signs of stereotyped sniffing movements (Fig 2) Similarly DOPA did not significantly increase the excitatory response to amphetamine alone in normal or in reserpinized rats which had not been injected with α-Me DOPA

The observation that, after prior treatment with α-Me DOPA, reserpine no longer modifies the pattern of amphetamine excitation in rats offers further evidence to that presented by Necina[2] and Day and Rand[3] that α-Me DOPA can in some way antagonize certain actions of reserpine, possibly by its metabolites taking over some of the physiological roles of their non-methylated analogues.

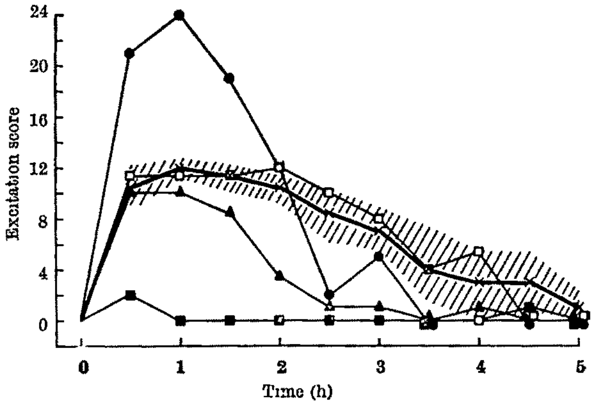

Fig 1 Time-course of the excitatory response to amphetamine in groups of 4 rats For scale, see text (maximum = 24) ×, Amphetamine only (shaded area = 95 per cent limits of error), ●, reserpine 18 h before amphetamine, ▲, α-Me DOPA 2 h before amphetamine; ■, reserpine 18 h, plus α-Me DOPA 2 h before amphetamine, □, α-Me DOPA 18 5 h plus reserpine 18 h before amphetamine

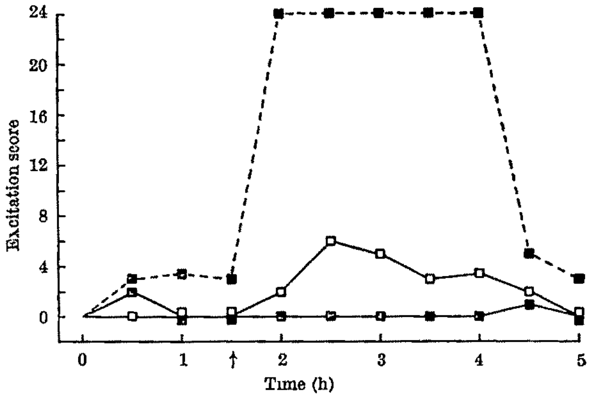

Fig 2 As Fig 1 ■——■, Reserpine 18 h plus α-Me DOPA 2 h before amphetamine, ■---■, reserpine 18 h plus α-Me DOPA 2 h before amphetamine plus DOPA injected at arrow, □——□, reserpine 18 h plus α-Me DOPA 2 h before saline plus DOPA at arrow

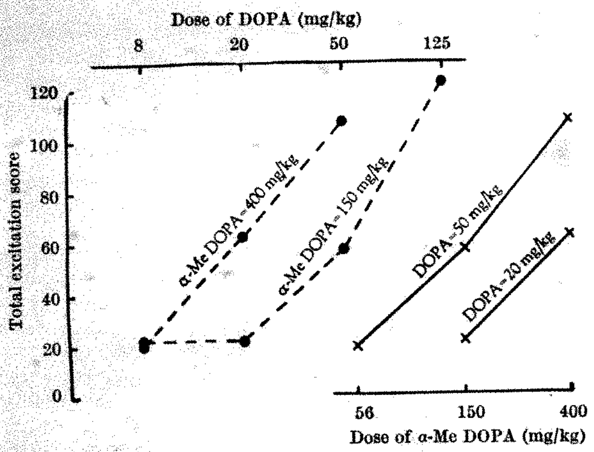

Fig. 3. Ordinate, total score for excitatory response to amphetamine in groups of 4 rats measured every 0·5 h from 2 to 5 h after amphetamine (maximum = 168); rats given reserpine 18 h and α-Me DOPA 2 h before and DOPA 1·5 h after amphetamine. Abscissæ, lower: dose of α-Me DOPA (solid lines); upper: dose of DOPA (broken lines)

(We have noted also that injection of α-Me DOPA before reserpine prevents the bradycardia normally induced by reserpine in rats, and in such animals a subsequent injection of imipramine no longer produces a marked tachycardia as it does in rats given reserpine only[1].) When α-Me DOPA is injected after reserpine and only 1–3 h before amphetamine, however, the combined treatment completely abolishes the excitant action of amphetamine. Under these conditions reserpine therefore appears to synergize the inhibitory action of α-Me DOPA, which is only slight by itself (although it can be increased somewhat by the use of higher doses than those reported here).

We have obtained certain indirect evidence which suggests that, in this test, amphetamine may act at least partly indirectly, via mechanisms involving catecholamines and/or 5-hydroxytryptamine. (For example, its action is markedly accentuated by imipramine-like drugs, and prolonged by MAO inhibitors; it is reduced by 5-HT antagonists, lysergic acid and brom-lysergic acid diethylamide, and abolished by tetrabenazine.) It seems reasonable, therefore, to suggest that the inhibition of amphetamine excitation by reserpine and α-Me DOPA may arise from a summation of their effects in depleting the brain of active amines. Possibly α-Me DOPA interferes with amine synthesis, binding or uptake at certain target sites of amphetamine action which are not entirely depleted of amines by reserpine (although tetrabenazine may deplete them fully). It appears unlikely that this action of α-Me DOPA is mediated purely by inhibition of amine synthesis by DOPA decarboxylase block (although such an action may contribute to its effect) since the potent decarboxylase inhibitor, 'Ro 4–4602' (ref. 4), does not mimic the action of α-Me DOPA in reserpinized rats.

The further phenomenon, of the restoration of the amphetamine response by DOPA after its inhibition by the combined action of reserpine and α-Me DOPA, presents greater difficulties of interpretation. No competitive antagonism between DOPA and α-Me DOPA seems evident, since the degree of excitation produced by DOPA in reserpinized rats in which the amphetamine response has been blocked by α-Me DOPA is directly proportional not only to the dose of DOPA injected but also to the dose of α-Me DOPA previously given (Fig. 3). If DOPA acts by overcoming an α-Me DOPA effect, the dose-response lines for these two substances would be expected to show opposite slopes. Furthermore, DOPA causes excitation in tetrabenazine-treated rats (in which the amphetamine response is blocked) only if α-Me DOPA has been given previously.

Perhaps this is a case where, under special conditions, a metabolite of α-Me DOPA (possibly α-Me dopamine, which may be considered as 3,4-dihydroxy-amphetamine) can be shown to exert a stimulant action; but the mode of action is obviously complex and demands further investigation.

We wish to thank Merck, Sharp and Dohme (Dr. J. Merry) for generous supplies of α-Me DOPA and Dr. H. Blaschko for helpful comments.

Neuropathological Changes in Chronic Cyanide Intoxication

The presence of a small metabolically active pool of cyanide in the body is now well established. The conversion of cyanide to thiocyanate was first demonstrated in 1894[1]. Although thiocyanate is the main excretory product of cyanide, it has been shown that it can also be oxidized to carbon dioxide and formate, and therefore cyanide-carbon can enter into the metabolism of one-carbon compounds. Using $Na^{14}CN$, it has also been shown[2] that the radiocarbon appears in the methyl groups of choline and methionine and in the ureide carbons of allantoin, and some of it also finds its way into the cyano groups of cyanocobalamin.

The enzymatic conversion of cyanide to thiocyanate was first investigated in 1933[3], nearly 40 years after the observation[1] that cyanide was excreted by animals as thiocyanate. The enzyme system was named rhodanese and it has been found to be specific for free cyanide without action on organically bound cyano groups. This property indicates that the excretion of thiocyanates after the administration of organic nitriles results not from a direct action on the nitrile itself, but from HCN which had first been removed from the nitrile molecule by another mechanism. More recent studies of the distribution of rhodanese in tissues[4] show it to be widely distributed in the body, activity being greatest usually in the liver. The demonstration of very large amounts of enzyme available as compared with the relatively small size of the fatal dose of cyanide raises the question of what limits cyanide detoxification *in vivo*. The suggestion has been made that this limitation may be set by the availability of sulphur, although it seems more likely that the rhodanese system is not geared to combat non-physiological doses of cyanide.

Although rhodanese is an efficient antidote against the toxic effects of cyanide, there exist other pathways by which this may be mediated or assisted. It has been shown that hydroxocobalamin takes up cyanide avidly to form the harmless cyanocobalamin and can protect the experimental animal against lethal doses[5]. Furthermore, a dietary deficiency of vitamin B_{12} leads to increased thiocyanate excretion and it has been suggested that competition exists between hydroxocobalamin and rhodanese[6]. Cyanide can combine with cystine *in vitro* to form 2-iminothiazolidine-4-carboxylic acid[7]. The formation of this acid also occurs *in vivo*, for on injection of potassium cyanide (1·5 μg daily) subcutaneously into rats, the acid can be isolated from the urine in quantities corresponding to 15 per cent of the dose, although the main excretory product (80 per cent of the dose) is thiocyanate.

As well as a mechanism for converting cyanide to thiocyanate, there exists a reverse pathway which has been called thiocyanate oxidase[8]. This enzyme, which is found only in the erythrocyte, has been detected in man, dog,

PHYSICS DEPARTMENTAL LIBRARY

rabbit and rats. The presence of thiocyanate oxidase, which ensures a persistent trace of cyanide in the blood, indicates that in minute quantities the latter is an essential metabolite.

From an experimental point of view, the role of cyanide has been invoked as of great importance in the possible ætiology of demyelination[9,10]. This work may be criticized on the grounds that the doses used were compatible with the production of lesions secondary to anoxia, due to interference with enzyme mechanisms of which cytochrome oxidase is possibly the most important. It was also shown that sodium azide in small doses could produce demyelination[9], and this work has been quoted[11] as being the only successful attempt at producing a demyelinating disease in animals at all comparable with those observed in man. In this connexion it is interesting to note that biochemically sodium azide has an action similar to that of potassium cyanide. However, azides do not occur naturally, and it is difficult to implicate them directly in human demyelination.

It seemed to us that the effect of much smaller doses of cyanide, with a greater time-interval between each dose, should be utilized in an attempt to produce central nervous system damage. Accordingly, two groups of three adult Wistar albino rats were taken, and the three experimental animals injected with 0·5 mg of potassium cyanide subcutaneously once weekly for 22 weeks. The other three were kept as normal controls. After this period of time the six animals were killed by lightly anæsthetizing with ether and severing the great vessels in the neck. Blood and livers were collected for vitamin B_{12} and folate activity and the brains extracted for histological examination.

The brains were processed in paraffin and stained with hæmatoxylin and eosin, luxol fast blue, and by the methods of Nissl, van Gieson, the phosphotungstic acid–hæmatoxylin stain of Mallory and with a silver stain for axons, Weil's myelin stain and sudan black. Frozen sections were stained with sudan IV.

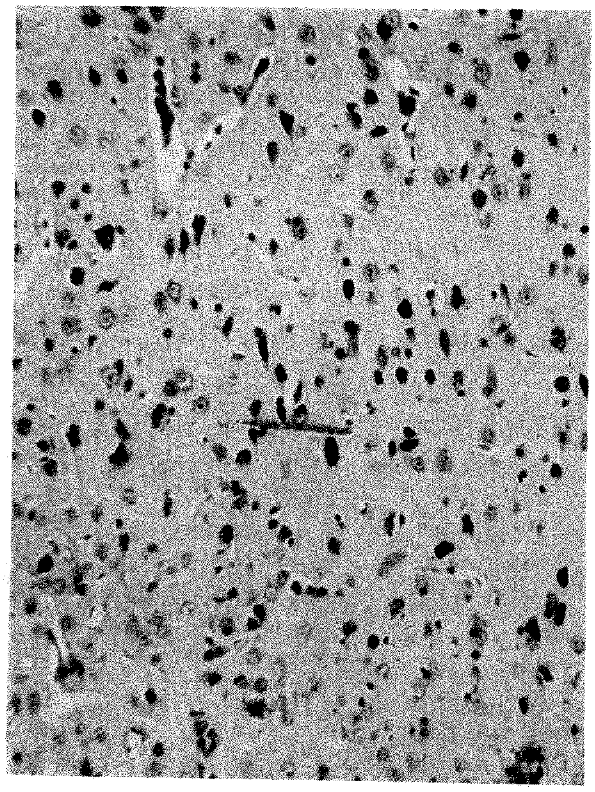

Fig. 1. Degenerated pyramidal cells in the cortex of a cyanide rat. (Hæmatoxylin and eosin × 400)

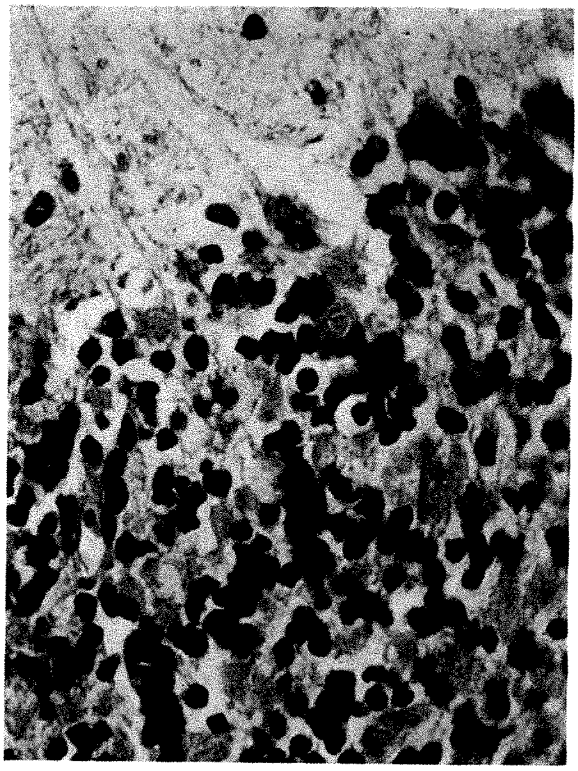

Fig. 2. Degenerated Purkinje cells in the cerebellum of a cyanide rat. (Hæmatoxylin and eosin, × 1,000)

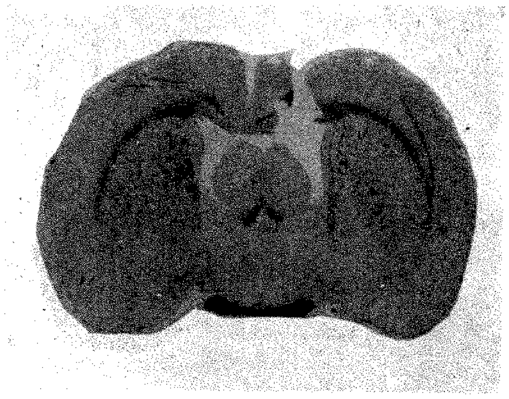

Fig. 3. Pallor of myelin in the corpus callosum of a cyanide rat. Compare the intact myelin in the optic chiasma. (Weil stain. × c. 3·3)

There are noticeable cellular changes in the cortex (Fig. 1), hippocampus and in the cerebellum (Fig. 2), with neuronal degeneration and cell loss in the brains of the animals receiving cyanide. There are minimal cellular changes in the brains of the normal controls, much less important than in the former group, and probably due to the anæsthesia. There is some pallor of myelin in the brains of the cyanide rats (Fig. 3), particularly in one of them, but whether there is demyelination is difficult to estimate.

The results of this small series indicate that cyanide in a comparatively small dose is capable of producing lesions in the central nervous system of the rat as described. In contradistinction to previous work along these lines, the animals tolerated the doses given without ill-effect or demonstrating manifest evidence of anoxia. It remains to be seen whether support has been given to the suggestion that a disorder of cyanide metabolism may be implicated in those diseases in which demyelination occurs within a picture of vitamin B_{12} deficiency[12]. We have been

Table 1

		Folate activity		B_{12} activity	
		Serum (μμg/ml.)	Liver (μg/g)	Serum (μμg/ml.)	Liver (μg/g)
(1)	Control	35·5	5·7	185	0·105
(2)	Control	27	5·3	110	0·182
(3)	Control	31	5·7	115	0·194
(4)	Cyanide	19	4·8	95	0·188
(5)	Cyanide	37·5	5·7	130	0·073
(6)	Cyanide	21·7	4·8	125	0·143

unable to confirm conclusively the observation[13] that cyanide intoxication probably produces depletion of liver hydroxocobalamin, although with the extremely small numbers used in this experiment it is impossible to make a valid comparison. Nevertheless, the average B_{12} activity of the livers in the cyanide treated rats is lower than that of the control animals (Table 1).

Further work requires the experiment to be repeated with the addition of cyanocobalamin and hydroxocobalamin to two groups subjected to a similar cyanide intake. If the latter confers protection to the central nervous system as opposed to the former then even greater questions of fundamental interest will be revealed.

HÆMATOLOGY

Use of Ion Exchange Resins to alter the Concentrations of Individual Inorganic Ions in Blood *in vivo*

As yet no simple method is available to alter selectively the concentration of any ion in blood perfusing an isolated organ. Such a method would be of considerable value, and we report on the development of a suitable procedure.

The method depends on the fact that an ion-exchange resin equilibrated with a known electrolyte solution will approximately reproduce the original ionic concentrations in a small volume of a second solution replacing the first. The technique described here has been developed to study the effect of varying calcium and magnesium concentrations in the arterial blood supplying the parathyroid glands.

The cation exchange resin 'Dowex-50' (a cross-linked polystyrene sulphonic acid resin containing 8 per cent divinyl benzene, 20–50 mesh size) is purified by repeatedly washing with 5 N hydrochloric acid and 5 N sodium carbonate alternately. The final sodium form is then washed with distilled water and air-dried at room temperature. A column containing 15 g (wet weight) of this resin is washed with about 10 l. of a solution containing 140 m.equiv. sodium/l. (as sodium chloride and bicarbonate), 3·8 m.equiv. potassium/l. (as potassium chloride), varying amounts of calcium chloride and magnesium chloride and bubbled with 5 per cent carbon dioxide in oxygen so as to give a *p*H of 7·4. The resin is then poured into a conical flask and swirled with the same fluid. It is finally transferred to a thick polyvinyl chloride tubing column (15 cm × 1·6 cm) with inlet and outlet tubes (0·4 cm diam.) guarded by fine stainless steel mesh. The column is rid of all air bubbles by running in the equilibrating fluid from below; it is used once only.

A suitable artery in a heparinized (4,000 units/kg) animal is tied off distally and secured proximally to the afferent tube of the column. The effluent blood is pumped directly into the desired vascular bed. By adjusting the calcium and magnesium concentrations in the equilibrating fluid it is possible to obtain with reasonable accuracy any concentrations of these cations in the blood coming off the resin column. The concentrations of sodium, potassium and hydrogen in the blood plasma are not affected significantly. Other workers have noted absence of changes in various chemical and cellular components of blood following its passage through the resin[1–3].

Table 1. CATION CONCENTRATIONS IN RESIN EQUILIBRATING FLUID, SYSTEMIC BLOOD AND EFFLUENT BLOOD IN DOGS

(the last-named values are representative of levels obtained with perfusion for more than 3 h)

Exp. No.	Specimen	Ca	Mg	Na	K	*p*H
		(m. equiv./l.)				
1	Equilibrating fluid	3·2	0·4	145	3·8	—
	Systemic plasma	5·8	1·2	151	3·7	—
	Effluent plasma	5·9	0·7	150	3·7	—
2	Equilibrating fluid	3·6	2·7	141	3·7	7·40
	Systemic plasma	5·9	1·5	151	4·1	7·39
	Effluent plasma	6·2	3·7	146	3·9	7·41
3	Equilibrating fluid	2·0	1·3	140	3·8	—
	Systemic plasma	5·5	1·9	—	—	—
	Effluent plasma	4·1	1·9	—	—	—
4	Equilibrating fluid	4·6	1·4	140	3·8	—
	Systemic plasma	5·6	1·9	—	—	—
	Effluent plasma	7·0	1·9	—	—	—
5	Equilibrating fluid	3·0	1·2	137	3·9	7·40
	Systemic plasma	4·6	1·4	147	4·4	7·38
	Effluent plasma	4·6	1·7	143	4·0	7·36

Cation concentrations were estimated by flame spectrophotometer (Zeiss *PMM* 12) and *p*H was measured anaerobically in a blood *p*H apparatus (radiometer *pHM*4 with macro-Astrup assembly electrode). Table 1 shows the concentrations of cations in the equilibrating fluid, systemic blood plasma and resin-treated blood plasma in dogs. It will be noted that the levels of calcium and magnesium in the equilibrating fluid produce different plasma-levels in the effluent blood because these elements are partly protein-bound. With the resin column described, it is possible to produce almost constant cation concentrations for more than 5 h with flow rates up to 5 ml. blood/min. Larger columns may be used for greater flow rates or longer perfusion periods.

It appears that similar methods could be used to alter the levels of other inorganic ions in blood using suitably pre-treated cation or anion exchange resins. Besides the perfusion of organs and glands, this selective addition or removal of various electrolytes in blood may have therapeutic possibilities.

We are indebted to Mr. W. J. Dempster and the staff of the Experimental Surgery Unit, Postgraduate Medical School, London, for their assistance.

Cross-relations of *Escherichia* and Human Red Cells

IT is well-known that certain strains of *Escherichia coli* (particularly 086:*B*7) are antigenically related to human red cell group A and group B substances. There have been differences in the results reported by different workers. Springer[1,2] found only anti-B activity in the sera of rabbits injected with *Escherichia coli* 086:*B*7 which was phenolized and then vacuum-dried. Using both living and treated preparations, Gonano *et al.*[3] showed both anti-A and anti-B activity, but in rather low titre, and their absorption studies gave rather disappointing results.

By the use of trichloroacetic acid extracts of *Escherichia coli* 086:*B*7, we were able to obtain sera with much higher anti-A and anti-B titres than resulted from the use of either formalinized or boiled-whole organisms. This suggests, *inter alia*, that the location of the antigens in the bacterial cell wall may be of importance[4]. The use of antigenic extracts also makes possible more detailed study of the antigenic relations and it is hoped to confirm and expand our impression that the cross-reacting *Escherichia* antigens are rather minor components of the cell.

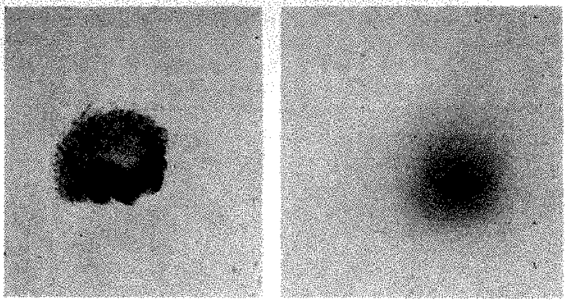
Male Specific Hæmagglutination in Mice

IT has been found that male skin grafts are rejected by female mice in the *C57BL* strain[1]. On the other hand, it has been well ascertained that an introduction of the histocompatibility antigens into inbred mice can elicit humoral antibodies to cause hæmagglutination of the donor red cells. This communication shows that the sera of female mice sensitized with male tissues can agglutinate specifically blood cells of intact male mice. *DD* strain mice were used for experiments. The female animals were subjected to the following treatment: A subcutaneous injection of 0·2 ml. testis-Freund's adjuvant emulsion per week for 4–6 weeks. Each of the injections contained 15–33 per cent testis homogenate. One to two weeks after the last injection the antisera were collected from the sensitized female mice, and kept at –20° C until the use for the present hæmagglutination test.

Blood cells from the intact male or female mice were collected in heparinized Tyrode solution, washed twice with it, and finally with Tyrode solution adjusted to *p*H 7·35. These cells were suspended in Tyrode solution to 2·5 per cent. For the test, the antiserum was thoroughly mixed up with the blood cell suspension in equal volume on a hollow slide. The mixture was incubated at 18° C. After 90 min, the hæmagglutination reaction was examined. For control, similar tests were performed to all the conceivable combinations of the sera and the blood cells of the non-sensitized *DD* mice.



1 2

Fig. 1. Hæmagglutination of intact male blood cells suspended in antisera of female sensitized with testis; (1) positive (*j*—6 antisera × ♂*c* blood cell); (2) negative (*j*—6 antisera × ♀*c* blood cell)

Out of 40 sensitized females remarkable spleen hypertrophy occurred in 20 animals, of which 7 animals had clear hæmagglutinations. As shown in Table 1, the sera from these 7 specimens agglutinate the blood cells of all males tested, but fail to react with those of females, except in 2 cases (Fig. 1). It is worth mentioning that no instance of reverse reaction was seen at all. Every reaction shown in Table 1 was easily reproducible. In the control series, using sera from non-sensitized animals, no hæmagglutination was detectable at all.

These results may suggest that the testis homogenate used for the injection might contain male specific antigen(s), against which the recipient female mice can produce humoral antibody(s) to agglutinate the blood cells of the male mice specifically.

It is clear that the 7 antisera shown in Table 1 were able to discriminate male blood cells from those of female; in other words, some immunological characteristics of blood cells differ between the sexes. (Such an exceptional case as ♀*b* obviously needs further investigation.)

We thank Prof. S. Asayama of this University for his valuable criticism, and Prof. T. S. Okada of the University of Kyoto for his advice.

PATHOLOGY

Induction of Fibrosarcoma in the Primate *Tamarinus nigricollis*

ATTEMPTS to induce malignant neoplasms in monkeys have not met with the success that has been achieved in other species. The rarity of spontaneous neoplasms in monkeys suggests that these animals are more resistant to the development of malignant disease than man and other species. There have been no specific references, however, to the use of the South American marmoset, *Tamarinus nigricollis*, in the experimental induction of neoplasms. A recent review by Kent[1] indicates that attempts at the production of malignant disease by the application of polycyclic hydrocarbons in monkeys have failed.

We injected 2 mg of 2-methylcholanthrene in olive oil subcutaneously into the forearm of 5 marmosets of the species *T. nigricollis*. Three animals, which died of upper respiratory infection approximately one month following the application of the carcinogen, showed no changes at the site of the implantation. One animal is still alive and exhibits no changes at the site of the methylcholanthrene implantation. One animal died of an upper respiratory infection 10 months following the injection of the methylcholanthrene. Gross examination of the skin over the site of the injection in the animal showed many small (0·5–1 mm) papules on the surface of the skin. When the skin was dissected over this area the subcutaneous tissue, which usually is less than 1 mm thick, was approximately 4 mm thick. It was firm and appeared to be attached to the underlying muscle. Histological examination of this material revealed numerous areas of pseudo-horn cysts as well as hyperkeratosis, acanthosis and papillomatosis (Fig. 1). This epithelial change is similar to, if not identical with, seborrhœic keratosis of man. The dermis rests on a highly cellular tumour composed of fibroblast cells. The nuclei vary in size, shape and staining qualities. Some nuclei appear spindle-shaped and others are round or oval, and occasional typical as well as atypical mitotic figures are seen (Fig. 2). This lesion has the histological appearance of fibrosarcoma, although it did not metastasize.

Because this type of reaction to methylcholanthrene is apparently rare in primates, I think it is important to report the finding now. Further work concerning the production as well as the transplantability of tumours produced in marmosets by methylcholanthrene and other polycyclic hydrocarbons is in progress.

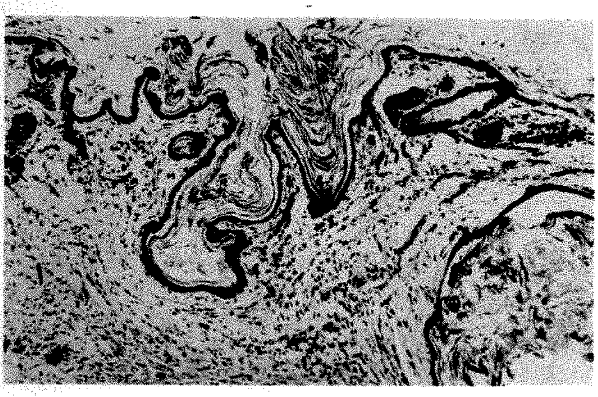

Fig. 1. Photomicrograph of skin illustrating the seborrhœic keratosis-like pattern of the epithelial change

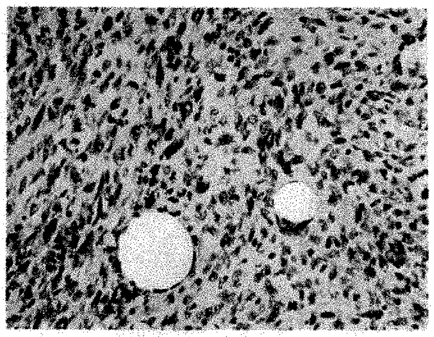

Fig. 2. Photomicrograph of the tumour showing pleomorphic fibroblastic cells with occasional mitotic figures

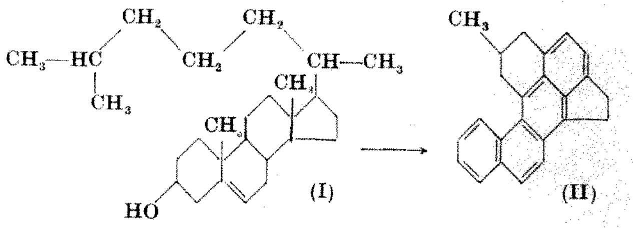
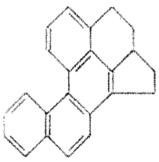
Particular Carcinogenic Activity of *F*-nor-Steranthrene

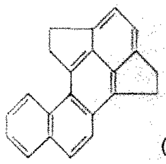
SINCE the discovery of the polycyclic chemical structure of cholesterol on one hand, and, on the other, of the carcinogenicity of 3-methylcholanthrene, it has often been postulated that certain types of cancer might be due to some abnormality in the metabolism of cholesterol and bile acids, resulting in the formation in the body of one or several carcinogenic polycyclic hydrocarbons[1]. Along these lines, Bergmann[2] pointed out the theoretical possibility for cholesterol (I) to be cyclized, with dehydration and dehydrogenation, into the hypothetical hexacyclic hydrocarbon (II), which he named 'steranthrene'



(since, the word 'steranthrene' has been used to designate the non-methylated basic hydrocarbon). Although experimental evidence for the existence of such a biochemical transformation is still lacking, it was of great interest to examine hydrocarbons of the steranthrene group for carcinogenicity. One of these hydrocarbons, 'angular' steranthrene (III), was recently investigated in mice by Dannenberg[3], and found to produce spindle-cell sarcomas by injection and epitheliomas by painting the skin; the substance showed approximately the same degree of activity as 3,4-benzopyrene and 3-methylcholanthrene. We report here the results of our experiments on another such hydrocarbon, *F*-nor-steranthrene (IV), the synthesis of which has recently been described[4].



(III)



(IV)

Mice belonging to strain XVII *nc/Z* (Radium Institute) were divided into four groups: 8 female mice aged 6 months; 7 females of 3–4 months; 7 males of 6 months; and 7 males of 3 months. They all received, by subcutaneous injection in the same area of the flank, 3 injections of 0·6 mg of substance (IV) in 0·2 c.c. olive oil, one month elapsing between each injection. Table 1 gives the results with the three first groups; the fourth group had to be killed before any tumour had appeared because of an outbreak of severe infection in the cage.

These results are of two-fold interest. They show: (1) That *F*-nor-steranthrene is an extremely potent

Table 1. CARCINOGENIC ACTIVITY OF *F*-NOR-STERANTHRENE

No. of animals	Date of appearance of first and last tumours	No. of animals developing tumours	Length of survival	Type of tumour
Group 1. ♀ Mice aged 6 months at start of experiment				
8	70–90 days	6	81–110 days	Mammary epitheliomas, 4 Epithelioma + sarcoma, 1 Sarcoma, 1
Group 2. ♀ Mice aged 3–4 months				
7*	85–90 days	6	100–126 days	Mammary epitheliomas, 2 Epitheliomas + sarcomas, 3 Sarcoma, 1
Group 3. ♂ Mice aged 6 months				
7	80–100 days	7	100–132 days	Sarcomas, 7

* One animal still alive with no tumour after 6 months.

carcinogen with a purely local action; given by subcutaneous injections, it induced the early development of fast-progressing sarcomas which provoked death in about 15 days; (2) that in the female mice, the cancer most frequently obtained and earliest to appear is an epidermoid parakeratotic epithelioma which starts in the excretory ducts of the mammary gland, and which is often associated with a sarcoma. All the stages of epidermoid metaplasia of the mammary ducts are observed, terminating in cancerization.

It should be noted that no spontaneous mammary cancer has ever occurred in the strain used, and none of the numerous carcinogenic hydrocarbons hitherto tested on mice of this strain had produced a mammary tumour; the only mammary carcinomas observed in this strain had been induced by X-rays and, as with *F*-nor-steranthrene, they were epidermoid epitheliomas of the mammary ducts[5].

We thank the National Cancer Institute (U.S. Public Health Service, Bethesda) for a grant.

Drastic Morphological Change without Loss of Viability in Ehrlich Ascites Tumour Cells after Incubation with Strongly Diluted Formaldehyde

As is repeatedly stated[1-4], living virulent Ehrlich ascites tumour cells (EATC) incubated several hours at 37° C in 0·9 per cent sodium chloride show normal appearance (round cell forms, Fig. 1) and do not lose their viability and virulence. But living virulent EATC, incubated at 37° C, 1–2 h, with strongly diluted watery formaldehyde solution, show a peculiar drastic reaction of their aspect without dying off. This reaction differs in principle from the damage caused by anti-Ehrlich-immuno serum, or severe osmotic damage which both lead to death of the cells.

Formaldehyde (35 per cent formalin) is diluted with 0·9 per cent sodium chloride or Krebs-Ringer phosphate buffer. The reaction shows up most clearly at a concentration of 3×10^{-3} M formaldehyde (0·0096 per cent solution). At 5×10^{-3} M the effect is much weaker.

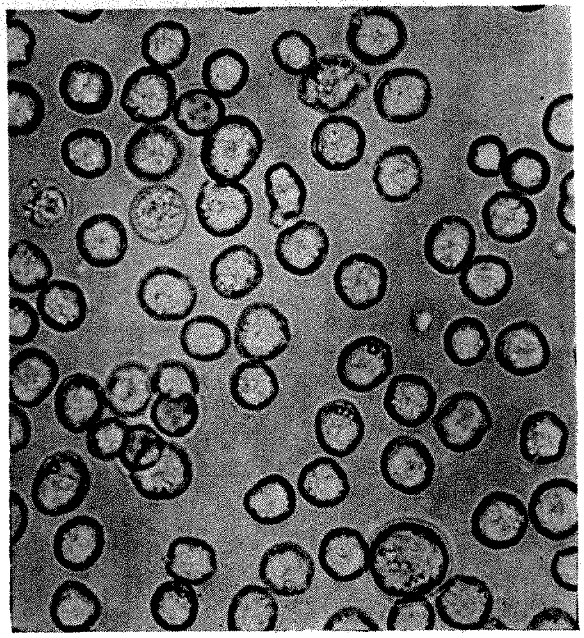

Fig. 1. Control: EAT-cells incubated 50 min in 0·9 per cent sodium chloride solution, 37° C. (× 610)

Sixty million virulent tumour cells (seventh–eighth day after transplantation) suspended in 0·9 per cent sodium chloride were incubated in 1·5 ml. of the formaldehyde solution of the concentration already mentioned at 37° C. After 10–25 min a part of the cells, increasing from 8 to 40 per cent, form short spicules. This gives cells the appearance of a thorn-apple (Fig. 2). Many spicules resemble fine droplets; the longer ones being swollen at their ends like clubs. On further incubation, the number of the thorn-apple-like deformed cells increases strongly; at the same time the spicules become longer and may change to long finger-like processes that may be nearly as long as the diameter of the cells. The longer processes may become curved or angular (Fig. 2, 2*A*); irregular swellings appear along the shaft, but especially at their ends.

The short, and also the longer, processes then grow into spherical drops of different sizes surrounding the cells in all directions.

For this phenomenon, that is, the formation of drops on the cell surface, we suggest the term 'stalagmosis' (stalagma = drop) (Fig. 3). As the size of the cells thus increases strongly, stalagmosis apparently is due to an intake of fluid, especially in the peripheral parts.

The maximal alteration of the cell (formation of 'thorn-apples' and drops) occurs after 50–60 min of incubation. At this time, most of the cells are surrounded on their surface with spicules, longish processes and drops of small to medium size. The content of the small processes and drops usually is homogeneous, but they often contain also vacuoles and—at the base—granules of cholesterol-esters (Fig. 3). The drop-like processes of the cells are originally always attached to the cell-body by narrow stalks.

In spite of the drastic alteration of the cells and the increase of the cell volume due to the processes and drop formation, formaldehyde of such small concentration does not cause any serious damage to the cell. This can be shown by the first fact, that added trypan blue does not stain the altered cells after incubation for 1 h (as in controls, there is only 5–8 per cent blue cells).

The viability and the unchanged virulence of the altered cells can be proved by the second fact, that their transplantation intraperitoneally into healthy mice leads to the death of the animals at the same time as in control animals, injected with untreated tumour cells (death of the mice between the twelfth and fourteenth day after transplantation with 3–5 ml. of ascites tumour; the mean survival time of control mice was 13 days).

After several hours of incubation of the EATC in the diluted formaldehyde solution the greater part of the deformed cells show morphologically a diminution of all processes. The cells which are still alive become spherical again, thus giving the usual aspect of EATC. Only in a part of the cells do the narrow processes and small droplets change into bigger drops. They continue swelling and finally rest with a broad base on the cell surface. If the death of the cells occurs after an incubation of 5 h and more, only about a quarter of the cells show diffuse swelling. The uptake of trypan blue slowly increases only after hours.

It was never observed that, using this concentration of formaldehyde, projections and drops separated themselves from the cells ('stalagmoptysis') as they do under the action of higher aliphatic aldehydes. This phenomenon will soon be described in detail elsewhere.

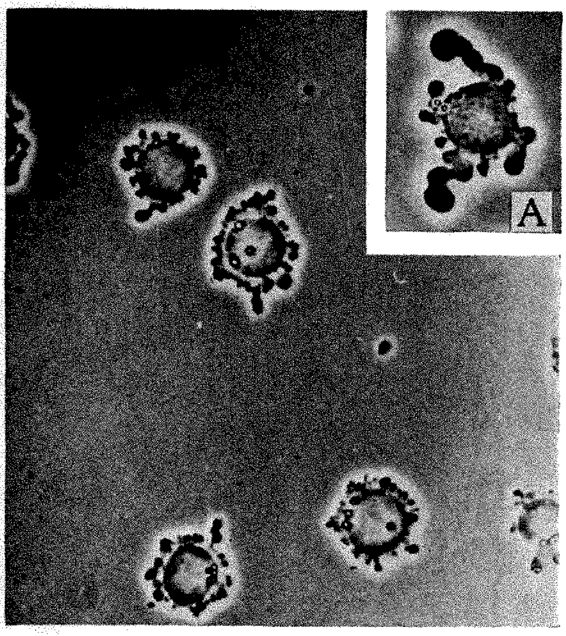

Fig. 2. EAT-cells incubated 20 min at 37° C in the diluted formaldehyde sodium chloride solution. All cells show spicules on their surface: 'thorn-apple' (× 690). *A*, Thorn-apple-like cell with long curved processes (× 710)

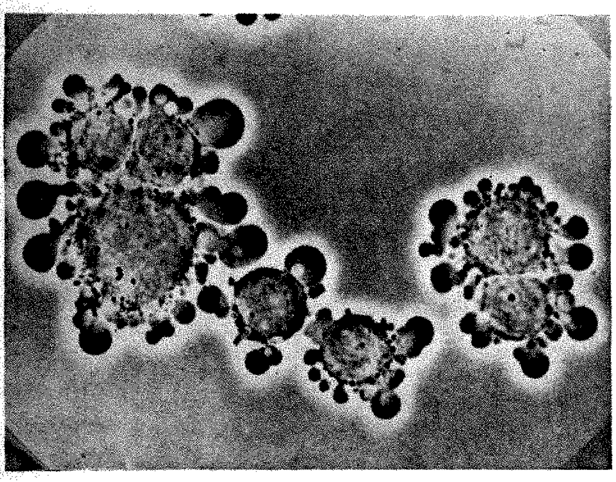

Fig. 3. EAT-cells, incubated 50 min 37° C in the diluted formaldehyde sodium chloride solution. 'Stalagmosis': all cells show small droplets and drops on their surface; many of them contain vacuoles or cholesterol ester-granules on the bases. (× 945 phase contrast)

The foregoing changes in morphology of the cell caused by highly diluted formaldehyde thus differ, both morphologically and biologically, from the irreversible alteration of the EATC due to osmotic disturbances (distilled water) or to anti-Ehrlich-immuno serum[4–6] since these agents cause in a few minutes diffuse membrane damage with much stronger swelling and enlargement of the cells whereby big and circular clear cytoplasmic 'blebs'[7] and 'blisters'[8] are formed surrounding the cytoplasma like yards (swelling yards). The result is the death of the cells through lysis within a short period of time[5].

IMMUNOLOGY

Antibodies in Thymocytes

Fragraeus was not able to show plasmocytes in normal thymus[1]; nor did she find plasmocytes in thymus after antigen injections[2]. After removal of the thymus in adult rats the antibody production is unchanged[3]. In spite of these results which ascribe no important influence on antibody production by the thymus there are still several clinical signs which lead to the conclusion that the thymus takes part in antibody production. Milton[4] has noticed a strong barrier between thymus and blood circulation; he found that this barrier must be damaged so that antigens can reach thymocytes. After thymectomy of newborn 5–12 days old mice Milton found no germinal centres nor plasmocytes in lymph nodes. The purpose of this investigation was to establish: (1) if there are cell-fixed antibodies in thymocytes; (2) if there is a difference between an antibody stimulation with pure antigens and antigens mixed with Freund's adjuvant and alum precipitated antigens.

For every kind of immunization, 10 male rabbits of 2,000–3,000 g body-weight were used.

Group I: Injection of bovine albumin three times a week. First injection (containing 3 mg albumin) was applied intraperitoneally; the later injections contained 1·5 mg and were given subcutaneously. After a course of 4 weeks' injection the animals received a booster injection of 3 mg albumin intraperitoneally 14 days after the last injection. Four days later the animals were killed and the blood and different organs were collected. Groups II and III received the same course of immunization but they were given only 1 mg protein. This protein was mixed with Freund's adjuvant in Group II and alum in group III. Group IV served as untreated controls.

The thymus was removed immediately after death of the animals and cut in slices 2 mm thick. These slices were incubated with Krebs–Ringer solution. Thirty min later, the cells were isolated by filtration through two layers of gauze and washed 4 times with Krebs–Ringer solution. The concentration of the cells was fixed to 10 million per mm^3. In every case the peripheral blood was controlled for cellular composition.

For measuring antigen absorption on thymocytes, one γ iodine-131 marked bovine albumin dissolved in 0·2 ml. Krebs–Ringer solution was added to 1 ml. of cells and this mixture was placed in an incubator for 1 h at 37° C.

Afterwards the cells were washed in Krebs–Ringer solution 4 times. After the last centrifugation the cells were resuspended in 1 ml. and their radioactivity determined in a scintillation counter. In every series 3 and 4 cases were investigated. The control animals were killed at the same time to maintain the same condition in respect to biorhythmical differences.

Data given by Sorkin, Rhodes and Boyden[7] have shown that methanol treatment of cells increases the ability of absorption of antibody-containing cells, but does not change the absorption through cells of untreated control animals. The methanol treatment was carried out as follows: after centrifugation of the cell suspensions at 1,200 r.p.m. by 4° C in 1 ml. of absolute methanol. After fixing for 5 min at room temperature, the cells were centrifuged again, twice washed with Krebs–Ringer solution and suspended in 1 ml. buffer solution. Bovine albumin (Swiss Red Cross) was used labelled with iodine-131 following the method of Dubert, Coursaget, Fallot and Royer[8].

For the precipitation test the classical methods of α- and β-precipitation were used[9].

The results are summarized in Figs. 1–3. Fig. 1 shows the absorption of radioactive marked bovine albumin on thymocytes. The amount is expressed in counts per min of 10^6 cells. Fig. 2 refers to the percentage of the absorbed albumin to the resting amount of radioactivity in the supernatant. Fig. 3 shows the absorption in respect to the DNA content; this means radioactivity counts per min with respect to 10 mg of thymus DNA.

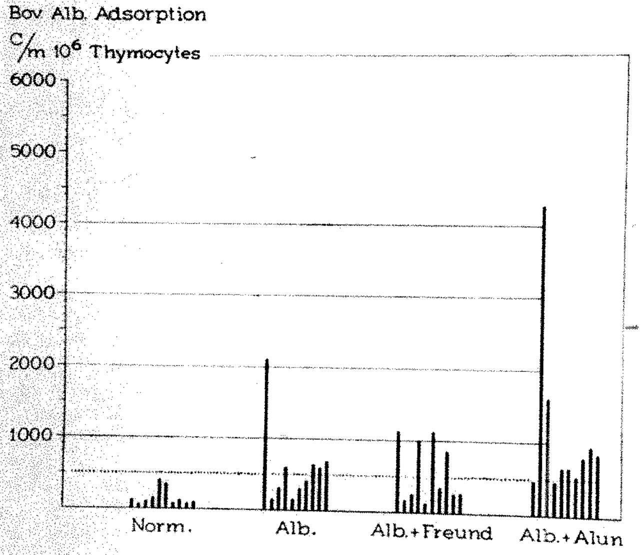

Fig. 1

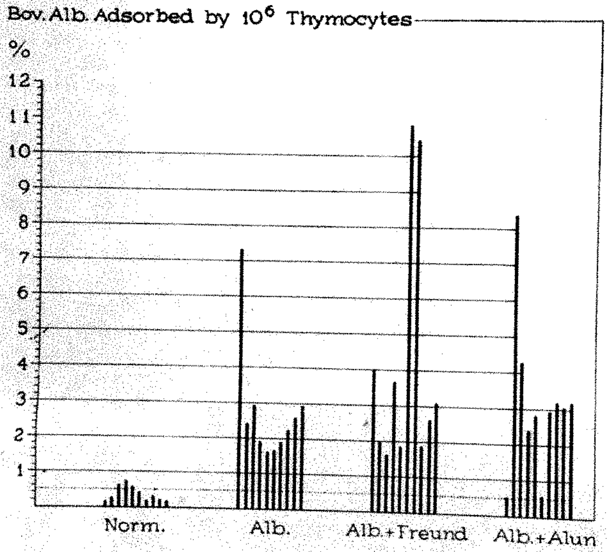

Fig. 2

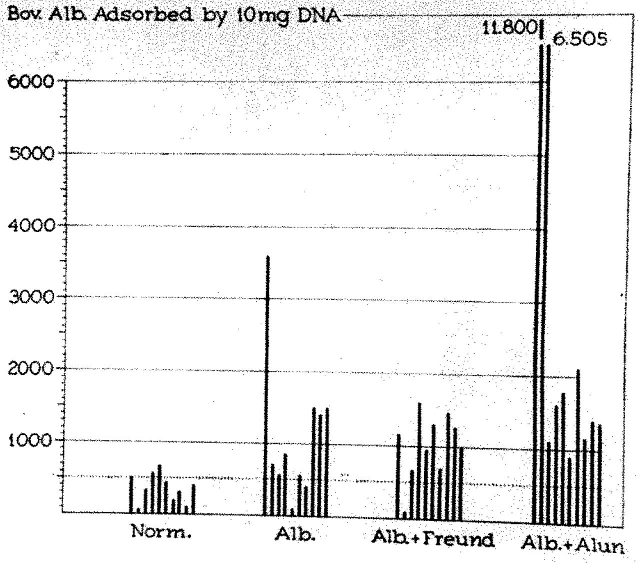

Fig. 3

The figures show clearly that the thymocytes of the hyper-immunized rabbits absorb significantly higher amounts of isotope-marked antigens than thymocytes of control animals. There is no highly significant marked difference between the variously immunized animals.

Experimental Allergic Thyroiditis in the Chicken

SINCE Rose and Witebsky's[1] demonstration of the auto-allergic disease affecting the thyroid gland of the rabbit, experimental allergic thyroiditis has been demonstrated in a number of mammalian species. However, auto-allergic lesions of the thyroid has not been heretofore produced in non-mammalian species. The work recorded here deals with the induction of thyroiditis in chickens by means of homologous thyroid tissue in complete Freund's adjuvant.

Thyroids were removed from normal Rhode Island Red chickens and 1 g aliquot was homogenized at 4° C in 5 ml. of 0·9 per cent saline. The homogenate was centrifuged at 800 r.p.m. for 5 min and the supernatant fluid lyophilized. The antigen-adjuvant emulsion was prepared thus: two parts of lyophilized thyroid extract dissolved in distilled water were mixed with one part of paraffin oil

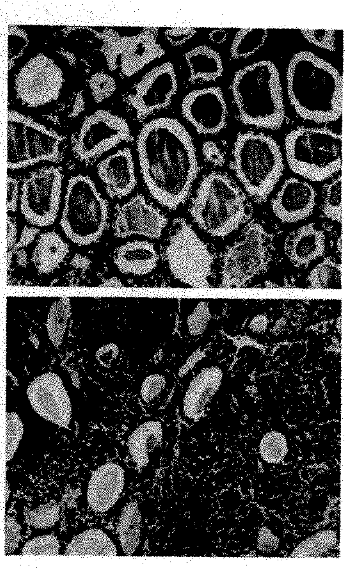

Fig. 1. Above, normal appearance of chicken thyroid; below, severely damaged gland in experimental allergic thyroiditis (× *c.* 20)

and one part of complete Freund's adjuvant. Adjuvant contained 1·5 vol. of 'Arlacel *A*', 8·5 vol. of paraffin oil and 12 mg/ml. of dried *M. tuberculosis*. Rhode Island Red chickens at the age of 10 weeks were injected subcutaneously by way of two foot-pads (a total of 5 mg of lyophilized thyroid extract per chicken). Skin tests were carried out 21 days after the sensitization. For this purpose homologous thyroid extract was prepared as described here and centrifuged for 1 h at 2,500 r.p.m. The supernatant fluid was injected intracutaneously in the wattle (0·1 ml. injection), and the reactions were observed at 24, 48 and 72 h. The birds were bled before death, serum separated, and anti-thyroprotein antibodies determined by passive hæmagglutination reaction[2] using tanned formalinized sheep erythrocytes. The cells were sensitized with saline extract of chicken thyroid in a proportion of 1 ml. of cell suspension to 0·5 mg of antigen. To meet the requirement of fowl antibody for complete precipitation, 8 per cent solution of sodium chloride was used as diluent[3]. The experimentation was terminated 30 days after the challenge injection, thyroid glands were removed, processed through paraffin embedding, and stained with hæmatoxylin–eosin and methyl-green-pyronine. The severity of thyroiditis was graded on an arbitrary scale ranging from ± to + + + +, based on the degree of infiltration of thyroid tissue with mononuclear cells.

Table 1. EXPERIMENTAL ALLERGIC THYROIDITIS, DELAYED HYPERSENSITIVITY AND ANTIBODY FORMATION TO HOMOLOGOUS THYROPROTEINS IN CHICKENS

Chicken No.	Severity of thyroiditis	Delayed sensitivity*	Reciprocal antibody titre
1	+	+ +	0
2	+ +	+	0
3	+	±	0
4	+ +	±	0
5	0	0	0
6	±	0	0
7	+ + + +	+ +	2
8	+ +	±	8
9	+	0	2
10	+	±	8
11	+ + +	+ +	0

* 48-h reaction.

Table 1 records the experimental allergic thyroiditis, delayed hypersensitivity and antibody formation to thyroproteins in chickens. Out of eleven birds, nine developed thyroiditis, and one chicken showed a few small aggregates of mononuclear cells (±). Eight control chickens, inoculated with complete adjuvant alone and killed 30 days later, did not show histopathological changes in the thyroids. There was a good correlation between the severity of disease and the intensity of delayed wattle reactions. Contrary to that, anti-thyroprotein antibody titres could not be correlated with thyroiditis.

Thyroiditis of moderate intensity was characterized by several foci of cellular inflammation located frequently in the peripheral areas of the gland. However, in advanced disease the lesions were quite diffuse (Fig. 1). The predominating cellular elements of a mild lesion were histocytes and lymphocytes, whereas in severe thyroiditis histocytes, lymphocytes, plasma cells, macrophages, polymorphonuclears, epithelioid cells and fibroblasts were found. The inflammatory process brought about the reduction in size of follicles, many of them being filled with histocytes, macrophages and leucocytes. In areas of dense mononuclear infiltration the follicles were totally destroyed. It should be mentioned that the histological appraisal revealed in one case the presence of a small ectopic thymus and a lymphoid mass resembling the germinal centre of the spleen. However, these lymphoid islands were clearly distinguishable from the cellular make-up of the thyroiditis lesions.

RADIOBIOLOGY

Influence of Lactation on the Retention of a Single Dose of Strontium-90 in Rats

IN previous investigations[1–3], it was found that the retention of radiostrontium after the lactation period (21 days *post partum*) was 45 per cent lower than that of virgin control rats when the isotope was injected into the pregnant rats 3 days before delivery. It was not clear, however, how much of this loss was due to a decrease in uptake of strontium-90 into bone or to other processes restricted to the time immediately after uptake or to a process still ruling after this initial period.

In contrast to the experiments already mentioned[1], in the experiment recorded here the isotope was injected within the day after delivery. The phase of initial incorporation into the skeleton was assumed to be finished before the third day after injection. At this time the amount of strontium in blood is less than 0·001 per cent of the injected dose and the retention in bone is declining[4–7]. Therefore, two groups of animals were killed 3 days, two further groups 21 days after injection of the isotope. This experimental arrangement allowed the estimate of net removal of strontium-90 from bone during this period by comparing radioactivity of the femora at these times.

Virgin rats and dams of the same age nursing litters of 4 juveniles were subdivided in groups as indicated in Table 1. The animals were albino rats of the Heiligenberg strain. 10 μc. of practically carrier-free strontium-90–yttrium-90 chloride contained in 0·5 ml. of physiological saline were injected intraperitoneally to each of the adult rats. Both femora of the females were ashed dry. Radioactivities and weights per femur are given in Table 1.

Retention of strontium-90 in the skeleton of the controls was 49 per cent of the injected dose (retention of skeleton = retention of femur × 20) 3 days after injection. At the same time, the nursing animals retained 41·6 per cent of the injected dose. Twenty-one days after the injection the radioactivities were 35 per cent of the injected dose for virgin

Table 1. RADIOACTIVITIES OF THE FEMORA OF NURSING AND VIRGIN RATS AT DAYS 3 AND 21 AFTER INCORPORATION

Experimental groups	No. of rats	Day of death after ^{90}Sr injection	Mean weights of animals at ^{90}Sr injection (g)	Ash weights per femur (mg)	Radioactivities % of injected dose*	
					per femur	per 100 mg ash of femur
Controls (not lactating)	5	3	194	220 ± 6	2·45 ± 0·12	1·09 ± 0·05
	10	21	191	239 ± 5	1·75 ± 0·09 71†	0·76 ± 0·04 67†
Dams (lactating)	5	3	214	246 ± 13	2·08 ± 0·09	0·86 ± 0·08
	7	21	215	220 ± 6	1·04 ± 0·07 50†	0·48 ± 0·03 51†

* Means with single standard deviation. † Percentage of amount of strontium-90 at third day after injection.

rats, 20·8 per cent for nursing rats. The difference of radioactivity relative to the injected dose, therefore, increased from 7 to 14 per cent during this time. Relative to the 3 days' value the retention of strontium-90 decreased 29 per cent within the control group, 50 per cent within the lactating group. Ash-weights of the femora of lactating animals relative to those of controls were found to be reduced at the end of the experiment ($P < 0·05$). The observed increase of the mean ash-weight of the femora of controls and the decrease of that of the nursing rats were not significant ($P < 0·1$). The concentrations of radioactivity decreased 33 per cent in the controls and 49 per cent in the lactating group.

The results demonstrate a considerable capacity of nursing rats to mobilize radiostrontium from their skeleton later than 3 days after injection of the isotope.

Biological Half-life of Cæsium in Man in Acute and Chronic Exposure

THE biological half-life of an element in man is needed for the calculation of maximum permissible concentrations in air and water of radioisotopes of the element[1]. An important assumption in making such calculations is that the body content during chronic exposure may be predicted by mathematical integration with respect to time of the equation describing the retention following a single acute intake. This hypothesis has never been tested in man. The results of recent investigations here demonstrate the essential correctness of the assumption for radioisotopes of cæsium.

In an investigation of the retention of cæsium in man, ten normal volunteer subjects took by mouth a single dose of 1 mg cæsium as the chloride, in aqueous solution containing about 0·6 μc. cæsium-132 and 0·1 μc. cæsium-134. The retention was determined by excretion analysis and by body radioactivity measurement[2], and during the 200 days that have so far elapsed it could be described by the sum of two exponential functions of time, of the general form:

$$R_t = (1-a)e^{-\lambda_1 t} + ae^{-\lambda_2 t}$$

where R_t is the fractional retention at time t days, a is a constant and λ_1 and λ_2 are biological elimination constants in day^{-1}. These findings are in agreement with those of others who have carried out similar investigations[3]. The values of a, λ_1 and λ_2 observed by us were somewhat variable among the ten individuals, and the means and ranges are shown in Table 1.

Table 1. VALUES OF a, λ_1 AND λ_2 AND THE CORRESPONDING BIOLOGICAL HALF-LIVES FOR TEN NORMAL SUBJECTS, FOLLOWING ACUTE EXPOSURE

	a	λ_1 day^{-1}	λ_2 day^{-1}	Biological half-lives τ_1 days	τ_2 days
Mean	0·928	0·693	0·00779	1·0	89
Range	0·88–0·95	0·577–0·866	0·00537–0·0119	0·8–1·2	58–129

The retention of radio-cæsium has also been determined by body radioactivity measurement in the cases of four men who accidentally acquired small burdens of cæsium-134 or cæsium-137. These measurements were begun too late to observe the short-lived component, but the retention decreased exponentially (for four years in one case) until the content had dropped below the limit of detection (for cæsium-134) or until it was no longer distinguishable from the contribution from fall-out (for cæsium-137). The values of τ_2 ranged from 109 days to 149 days[4,5].

When chronic exposure continues for several biological half-lives, the body content, q, increases to an equilibrium value q_∞ given by the equation:

$$q_\infty = m\left(\frac{1-a}{\lambda_1} + \frac{a}{\lambda_2}\right)$$

where m is the daily intake in the same units as q. From the values in Table 1 we see that:

$$\frac{1-a}{\lambda_1} \ll \frac{a}{\lambda_2}$$

and to a close approximation:

$$q_\infty = \frac{ma}{\lambda_2}$$

The presence in man of fall-out cæsium-137 from the food-chain affords an opportunity for the determination of λ_2 from measurements of q[6,7] and m, provided it can be ascertained that the subject is in equilibrium with the diet, that is, that q is not changing when the measurements are made. An alternative to the difficult determination of the daily intake is to measure the daily total excretion, averaged over several days[4]. This has been done for two of the ten subjects of our study, and the results are shown in Table 2; the results for another subject are also included. In calculating the values for λ_2 for subjects R and M, the values shown for a were those obtained from the study following acute exposure. When individual values for a are unknown, adoption of an average value of 0·93 (as in the case of subject C) introduces no greater error than 5 per cent in the values for λ_2 and τ_2. In April 1959 the levels of fall-out cæsium-137 *in vivo* were increasing[6] and subject R was therefore not in equilibrium with his diet. This had the effect of making τ_2 lower than the true value. It should also be noted that the urinary/fæcal excretion ratios for subjects R and M (8·4 and 5·0 respectively) were the same, within experimental error, as in the acute exposure study (8·6 and 5·3 respectively). This showed that the fraction transferred

Table 2 BIOLOGICAL HALF-LIFE OF CÆSIUM IN THREE MEN CALCULATED FROM BODY CONTENT AND MEAN DAILY EXCRETION OF FALL-OUT CÆSIUM-137

	Subject *R* April 1959	Subject *R* April 1961	Subject *M* April 1961	Subject *C* April 1961
q (mμc)	5 5	2 55	6 4	7 65
m (mμc /day) (urine + fæces)	0 081	0 036	0 051	0 042
a	0 885		0 93	0 93 (assumed)
λ_2 (day^{-1})	0 0130	0 0125	0 0074	0 0051
τ_2 (days)	53	55	94	136
τ_2 (days) (from acute exposure study)	58		100	—

from the gastro-intestinal tract to the blood, of cæsium-137 ingested in food, was at least 0 9

The good agreement between the values for τ_2 determined by the two methods validates the integrated form of the acute exposure retention equation as applied to chronic exposure The detailed results of the acute exposure study will be published elsewhere

BIOLOGY

Second-day Minimum in the Growth Curve of Mice subjected to Magnetic Fields

IN a previous communication[1] it was shown that strong static magnetic fields retard the growth of young mice The maximum weight difference, relative to identically housed controls, is reached after 10–12 days of residence in a homogeneous field of 4,200 œ strength In the first such experiments, conducted in 1948 in the Institute for Experimental Physics of the University of Budapest, as well as in the twelve subsequent experiments conducted on several hundred mice in the laboratory of the Biomagnetic Research Foundation in Evanston, Illinois, a sharp drop in the weight of the mice was observed on the second day of residence in the field, followed by a steep increase up to the base line

To investigate this 'shock effect' of the magnetic field, six 20-day-old female *IRC* strain mice were conditioned for 18 days to the 3$\frac{3}{4}$ in diameter and 1$\frac{7}{16}$ in high cages, used in the electromagnet and in the dummy magnets alike The cages had automatic water and food supply (Rockland Mouse Diet), the floor of the cages was a copper plate covered with 'Mylar', thermally insulated from the lower pole (or the simulated pole of the dummy magnets) and kept through a thermocirculator at 28° C Between cage wall and floor a circular opening provided free movement for the tails of the mice and helped to sweep excrements and food remnants from the cage area When the Varian 4-in electromagnet was energized, it produced a field of 9,400 œ in the centre of the cage and 8,900 œ, 0 5 in from the cage wall The average paramagnetic strength of the field was, therefore, about 1 5 mega-œ²/cm Water cooling of the electromagnet kept the magnet poles 2° below the room temperature of 23° C The dummy cages, situated 2 ft from the magnet, had identical lighting and ventilation conditions

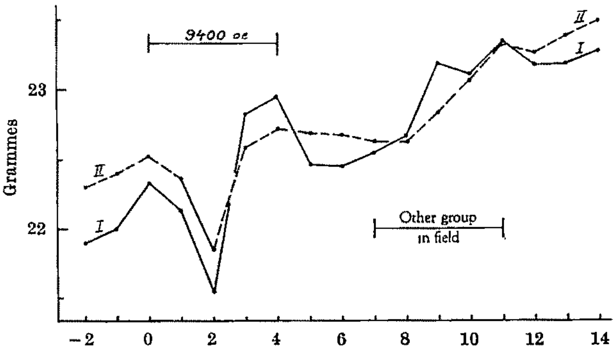

Fig 1 Average growth curve of two groups of mice, alternately exposed each 14 days, for 196 h, to a vertical field of 9,400 œ

The six animals were divided into two groups, three in the magnet cage and three in the dummy magnet cage The following sequence was adopted The magnet was energized from 4 p m Monday until 4 p m Friday, when the magnet group was similarly placed in a dummy magnet cage On the following Monday the previous dummy group was placed in the field from 4 p m Monday until 4 p m Friday and the sequence repeated The weight of the mice was individually measured to 0 1 g every day at 4 p m , when the cages were cleaned

With this schedule, the same group was treated every 14 days for 196 h in the field The 14-day cycle was repeated 5 times and covered the age-period of 5–16 weeks Group I mice started and finished the 5 cycles one week earlier than group II mice, therefore, their average age and weight are less and their average growth rate slightly higher Fig 1 shows, for each group separately the average weight variation during the 14-day cycle It can be seen that the second-day minimum is definitely present The average weight difference between zero hour and 48 h in the field is −0 95 ± 0 29 g, and the difference between 48 h and 96 h in the field is +0 99 ± 0 37 g (Both corrected for average daily weight gain) The existence of the second-day minimum is thus established on a probability-level of 1 3,000 The magnitude of the minimum does not decrease in subsequent cycles, proving that the mice do not get adapted to the 'shock' of the magnetic field, if repeated every 14 days It seems that an after-effect of the field prevails for four days after removal, since during this time the normal growth is arrested

The experiments were partly supported by graduate research grant No 56–92–36 of the University of Illinois

Loss of Liver Cell Antigens in Azo-dye Induced Hepatomas of Rats

THE immunizing ability of several chemically and virus induced tumours and immuno-chemical studies suggest that neoplasms of animals and man are characterized by a changed antigenic composition[1-3] As yet however, no regularity in these changes has been observed, probably due to the small amount of data available It remains unknown whether the cell type of a tumour, the carcinogens used for tumour induction, or the genetic composition of the neoplastic cells affect the kind and degree of these antigenic changes To obtain information about some of these problems we compared the loss of liver antigens in fourteen hepatomas Although these tumours were selected on the basis of the histological features characteristic of hepatomas it is doubtful whether they are strictly comparable. First, the deoxyribonucleic acid (DNA) content of the stemline is not the same in different hepatomas This agrees with our previous observation that even two hepatomas of the same liver lobe can consist of cells with different DNA values[4] Secondly, some of these hepatomas consist of a uniform population of cells whereas others are characterized by a heterogenous population of cells with varying amounts of DNA

Antibodies against liver antigens were produced by four weekly subcutaneous injections of liver homogenates emulsified with equal parts of Freund's complete adjuvant (Difco) into rabbits All antisera have been absorbed with rat sera The antigens have been prepared from saline-perfused livers and hepatomas The antigen-antibody reactions were examined in micro-diffusion plates[5], using 1 per cent agar in buffered physiological saline, and plastic templates for the reactants[6] The absorption was done by placing the absorbent antigen into the wells of the templates before the addition of antiserum The hepatomas were induced in male rats of the Sprague-Dawley strain by the feeding of 4-dimethylaminobenzene (DAB) containing diet. The diet was discontinued 3 weeks before samples were taken

The results shown in Figs 1 and 2 indicate that the hepatoma cells have lost some antigens present in the normal liver of adult male rats This conclusion is based on the following observations Anti-liver serum absorbed with normal liver does not produce precipitin bands when tested against liver antigens, rat serum and hepatomas respectively However, anti-liver sera absorbed with hepatoma-($AL+H1$) produced at least five well-defined precipitin bands when tested against normal liver, but none against rat sera (Fig 1), indicating that the obtained precipitin bands represent antigens associated with normal liver The same anti-liver sera ($AL+H1$) was tested against fourteen hepatomas of different rats Seven samples of the result obtained are shown in Figs 1 and 2 The presence of one ($H5$, $H6$), two ($H9$, $H14$) and three ($H12$) precipitin bands indicates that not all hepatomas have lost the same number of antigens

The present results indicate either a loss or a decrease of liver antigens in hepatoma cells This conclusion is based on the assumption that parenchymal cells were the source of hepatomas and of the antibody producing antigens These observations agree with the results obtained by immunofluorescence techniques on a variety of neoplasms including hepatomas of rats[7], kidney carcinomas of hamsters[8], squamous cell carcinomas of human skin[9] and carcinomas of the human intestine[10]. Thus it appears likely that the loss or decrease of antigens in neoplastic cells is a widespread phenomenon. Considering that most, if not all, of the afore-mentioned tumours consist of cells with an abnormal chromosome complement and (or) an abnormal amount of DNA[11], the question arises whether a correlation exists between the loss of antigens and the alteration of a genome In this connexion it is of interest to note that the examined hepatomas differ not only by their DNA modal values but also by the number of antigens lost

Rapid Changes in Transpiration in Plants

I SHOULD like to put forward a different interpretation for the experiment illustrated in Figs 2 and 3 of the recent article in *Nature* under the above title[1] It may be presumed that at the start of the second part of the experiment (Fig 3, Curve II) the leaves in the cuvette C of Fig 2 were not flaccid or such an important fact would have been mentioned, therefore the suction pressure in the transpiring mesophyll cells must initially have been less than the full osmotic pressure of their vacuolar sap. and this in turn must have had a value much lower than the 40 atmospheres or so exerted by the 1 M sodium chloride solution (here assumed to be at 20° C) which replaced the water in vessel B The latter change therefore caused a considerable suction pressure gradient *down* the plant from the leaf mesophyll cells to the solution in B and water must have moved out of the roots into the salt solution—any increase in water permeability of the roots would only accelerate this water loss At the same time the mesophyll cells continued to transpire, and at an enhanced rate, as shown by the curve They must, therefore, have been losing turgor rapidly

The simplest hypothesis is that the early changes in transpiration rate were due to stomatal movements, and the mechanism suggested for these[2] is based on Darwin and Pertz[3], namely, the increase in suction pressure of the wilting mesophyll cells withdraws water from the epidermal cells, including the subsidiary cells, and the rapid loss of turgor of the latter allows the guard cells to bulge outwards, opening the stomatal pores, closure then follows as the subsidiary cells, by virtue of their increased suction pressure, withdraw water from the guard cells Such 'passive' stomatal opening is not observed with gradual wilting, it may be supposed that under these conditions the suction pressures in subsidiary cells and guard cells remain so near to equilibrium that no opening movement can be detected but only the gradual closure with loss of guard cell turgor Presumably for curve I (Fig 3) the water-strain imposed by dipping the tip of a single leaf in 1 M sodium chloride was much less than that due to the immersion of the whole root-system in it, but the fact that the initial rate of transpiration was equal to the maximum of curve II also suggests that the stomata may already have been as wide open as was mechanically possible

It seems essential to follow the course of stomatal movement, as well as of transpiration, if such experiments are to help elucidate the so-called 'Ivanoff effect'[1] It may well be, for example, that the leaves of conifers, mentioned earlier in the article as not showing this effect on transpiration, do not have the initial 'passive' stomatal opening on wilting because of their rigid structure and thick epidermal cell walls

The 'Ivanoff effect' on transpiration when a leaf is detached in air must be in part due to the initial stomatal opening and in part to release of tension in the xylem sap The latter contribution is, however, likely to be extremely small Even if we suppose that the mesophyll cells were just flaccid before excision, with a vacuolar osmotic pressure of, say, ten atmospheres, and that they at once became fully turgid when the petiole was severed, a simple calculation will show that the vapour pressure in equilibrium with their suction pressure would increase only by 0 8 per cent With an ambient relative humidity of, say, 70 per cent, the transpiration would only increase 2 7 per cent if the stomatal resistance did not change This is obviously an over-estimate, for the cells could not become fully turgid while transpiration continued

O V S HEATH

University of Reading,
Horticultural Research Laboratories,
Shinfield Grange,
Shinfield, Berks

[1] Rufelt, H , *Nature*, **197**, 985 (1963)
[2] Heath, O V S , in *Plant Physiology*, edit by Steward, F C , 2 (Academic Press, New York, 1959)
[3] Darwin, F , and Pertz, D F M , *Proc Roy Soc* , B, **84**, 136 (1911)

PROF HEATH's interpretation of my results is based on a hypothesis which, according to my experiments, is no longer valid He assumes that water transport in the plant is mediated by a cell-to-cell mechanism and that it is the suction potential of the mesophyll cells which determines the rate of water movement through the plant I imagine water transport from the root to the atmosphere in easily movable columns in the xylem and cell walls The rate of transport then depends on the gradient of suction potential from the root medium to atmosphere and the permeability or resistance to water movement of the intervening stages The cells of the plant obtain their water from the cell wall reservoir The uptake of water does not depend on the suction potential of the mesophyll cells but on that of the air in the intercellular spaces, which is a function of that in the ambient air and the stomatal resistance However, as the water content of both the mesophyll cells and the guard cells, at equilibrium, is determined by the cell-wall water potential (referred to earlier[1] as the cell-wall water deficit), the impression is obtained that the guard cells are regulated by the mesophyll cells When equilibrium does not occur, as can happen when a stress is suddenly released, the water content of the guard cells and the mesophyll cells may vary independently, if they have different permeabilities The results which have been obtained experimentally agree with the supposition that the guard cells are more permeable than the mesophyll cells

On the assumption that it is the suction potential of the mesophyll cells in the leaf which determines water uptake, Heath has supposed that the addition of sodium chloride to the root medium to raise the osmotic pressure to 40 atm must result in a suction pressure gradient down the plant and water movement in the same direction. On the same assumption, one might expect the same result when a shoot or leaf is cut off or the petiole lifted out of water, since the cut surface is exposed to the much lower water potential of the air However, as shown in my Table 1 and by Allerup and Nielsen[2], movement of water continues up towards the leaf We have many times obtained the transitory increase in transpiration in response to increases in the osmotic pressure of the root medium of 1–5 atm (refs 3 and 4) which could not, even on Heath's supposition, reverse the gradient of suction potential. I would suggest that the suction gradient is always in the direction of water movement up the plant in the examples under discussion because of the much lower water potential of the ambient air

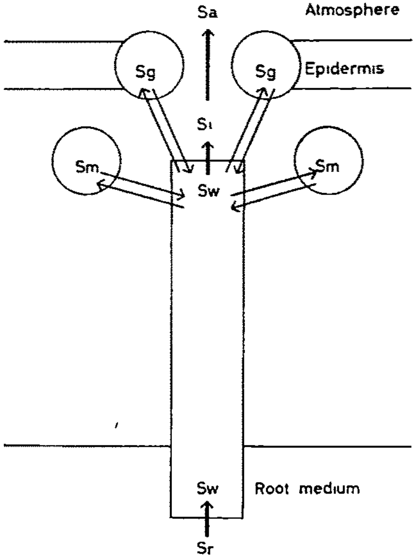

Fig 1 Schematic representation of water transport in a plant Suction potentials in root medium (*Sr*), cell wall system (*Sw*), intercellular spaces (*Si*), surrounding air (*Sa*), guard cells (*Sg*), mesophyll cells (*Sm*)

A large increase in suction potential in the root medium of 40 atm gives rise to a corresponding increase in suction potential of the water in the leaf cell walls and intercellular spaces It is the latter suction potential which causes water stress in the plant and not the suction potential of the vacuolar sap in the mesophyll cells, this increases secondarily In a severed leaf there is no need for full turgidity before the transitory opening of the stomata occurs That turgidity does not in fact increase is shown by the determinations of relative turgidity (Table 1) When the full effect of the sodium chloride is realized, the increase in cell-wall water deficit causes reduction in stomatal aperture As the permeability barrier in the root can scarcely be exposed to the solution of high concentration instantaneously (the water in the AFS will dilute the solution), I suppose that the decrease in water uptake is preceded by a temporary increase due to an increase in root permeability This makes it possible to explain the Ivanoff effect and the increase obtained by addition of an osmotically active substance in the same way

In Fig 1 the proposed idea is summarized in a simplified form The main pathways of water are indicated by the arrows At the root barrier, the evaporation boundary between cell wall and intercellular spaces, and the diffusion barrier in the stomatal openings, the transport is illustrated by single arrows because it can be presumed to take place in practice only in one direction, whereas dynamic equilibria normally exist between the cell-wall reservoir and the vacuoles of both the mesophyll cells and the guard cells Transport to mesophyll cells and guard cells differs only in that the latter takes place faster, facilitated either by higher permeability or a metabolic driving force

MICROBIOLOGY

Accumulation of Oxytetracycline Relevant to its Bactericidal Action in the Cells of *Escherichia coli*

IN the course of work on the effect of oxytetracycline on the growth of *E coli B*-151-1 using a nepherometer, we observed a remarkable increase in turbidity when the cells were incubated at high concentration of oxytetracycline over 100 μg/ml in nutrient broth Results showed that this increase in turbidity was not caused by the increase of number of cells, but was due to a remarkable accumulation of oxytetracycline in the cells of *E coli* Cells of *E coli B*-151-1 or *E coli K*-12 were collected from 15–16 h culture by shaking at 30° C in nutrient broth (*p*H 7 2), and were washed twice with distilled water Usually Monod's test tube was used for both growth and accumulation tests unless otherwise indicated Usually, cells of *E coli* (about 1 mg dry weight) were suspended in 10 ml of medium in 30 ml Monod's test tube, and the tube was shaken at 30° C on a shaking machine The resting cells were incubated with various concentrations of oxytetracycline in nutrient broth (*p*H 7 2) at 30° C, and the growth was measured using a Kotaki nepherometer The amount of oxytetracycline was expressed as that of its hydrochloride

The increase in turbidity began immediately as if the cell growth were promoted in the presence of high concentration of oxytetracycline (100–400 μg/ml) Microscopic counting analysis, however, showed that the number of cells did not increase during the incubation The cells incubated with high concentration of oxytetracycline became yellow because of an abundant accumulation of oxytetracycline, and they were found to have higher electron density than the normal cells by electron microscopic examination Further experiments were carried out using a nitrogen-free simple medium containing 1 per cent glucose, 0 2 per cent K_2HPO_4 and 0 02 per cent $MgSO_4 7H_2O$ The *p*H of the medium was adjusted to 6 5 As shown in Fig 1, the increase in turbidity was remarkable when the cells were incubated with glucose, K_2HPO_4 and $MgSO_4$ Without glucose or $MgSO_4$ the increase in turbidity was little When the heat-treated cells (1 min in boiling water) were used instead of intact cells, we did not observe any appreciable increase in turbidity, and the same result was obtained when the incubation was carried out without the cells The presence of K_2HPO_4 seemed unnecessary for increase of turbidity since a large amount of such increase also occurred in the presence of glucose and $MgSO_4$ of the *p*H of the medium was about 6 5 Usually K_2HPO_4 was used for its buffer action

After incubation, the cells were centrifuged and washed with distilled water once and were then suspended in 5 ml of distilled water When the cells were heated in the boiling water, a large decrease in turbidity was observed only for the cells which were incubated with high concentrations of oxytetracycline in the medium containing glucose, K_2HPO_4 and $MgSO_4$ Electrophotometric analysis showed that the absorption spectrum of the boiled extract and that of heated oxytetracycline hydrochloride solution were almost identical Based on these results, we usually estimated the accumulated oxytetracycline by measuring the optical density at 340 mμ or 260 mμ of the extracts obtained by boiling the cells which accumulated oxytetracycline with water for 5 min and comparing its value (*A*) with that of the standard oxytetracycline solution which was also heated in the same condition The endogenous value (*B*) was determined with the boiled extracts of cells which were incubated without oxytetracycline and was subtracted from the value (*A*) giving the amounts of oxytetracycline accumulated (*A*–*B*) This value well indicated the relative amount of oxytetracycline accumulated, although it may not show the exact amount of oxytetracycline accumulated

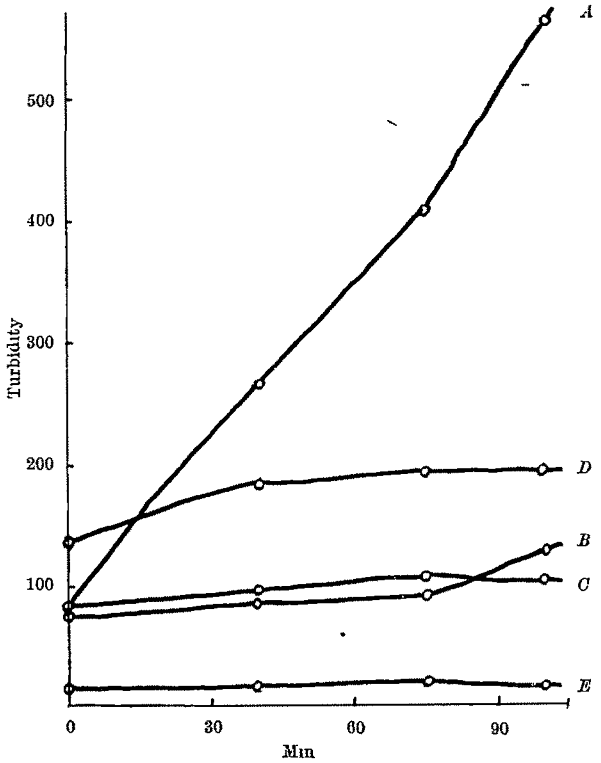

Fig 1 Increase in turbidity of cells of *E coli B*-151-1 owing to accumulation of oxytetracycline Reaction mixture contains 1 ml cell suspension (1 6 mg dry weight) 1 ml oxytetracycline hydrochloride solution (4 mg/ml) and 1 ml of 10% (w/v) glucose, 2% K_2HPO_4 (*p*H 6 5), 0 1% $MgSO_4 7H_2O$, respectively, in the total volume of 10 ml Medium *A*, glucose 1%, K_2HPO_4 0 1%, $MgSO_4 7H_2O$ 0 01%, *B*, glucose 1%, K_3HPO_4 0 2%, *C*, K_2HPO_4 0 2%, $MgSO_4 7H_2O$ 0 01%, *D*, glucose 1%, K_2HPO_4 0 2%, $MgSO_4 7H_2O$ 0 01% (heated cells), *E*, glucose 1%, K_2HPO_4 0 2%, $MgSO_4 7H_2O$ 0 01% (without cells)

Table 1 ACCUMULATION OF OXYTETRACYCLINE IN *E coli B*-151-1

Incubation condition was the same as described in Fig 1 The amounts of oxytetracycline was measured from the value of optical density at 340 mμ of boiled extracts of the cells which accumulated oxytetracycline

Medium	Incubation time	
	40 min	100 min
A	305 μg/mg dry weight	464 μg/mg dry weight
B	35	99
C	70	75

From the results shown in Fig 1 and Table 1, it is apparent that oxytetracycline remarkably accumulated in the cells of *E coli*, and consequently the turbidity of the cells greatly increased when the cells were incubated with high concentration of oxytetracycline in the medium containing glucose, K_2HPO_4 and $MgSO_4$ This may be the first indication of accumulation of large amounts of oxytetracycline in bacterial cells Optimum *p*H for the accumulation was about 6 5 At a low temperature, such as 2° C, the accumulation was very small Since glucose was needed for the accumulation, supply of energy seemed to be necessary This speculation was supported from the experiment using inhibitors Metabolic inhibitors such

Table 2. CORRELATION OF PROMOTION BETWEEN OXYTETRACYCLINE ACCUMULATION AND ITS BACTERICIDAL ACTION

Incubation was carried out using Monod's test tube in aerobic condition at 30° C for 90 min Monod's test tube contains glucose, K_2HPO_4 (*p*H 6 5), $MgSO_4 7H_2O$, oxytetracycline and the cells of *E coli K*-12 (1 mg dry cells) as shown in Table 2 in a total volume of 10 ml

Incubation medium	Oxytetracycline added	Oxytetracycline accumulated per mg dry cells	Viable cells/ml	Viable cells (%)
Glucose 1% K_2HPO_4 0 2% $MgSO_4 7H_2O$ 0 01%	—	—	$3\ 31 \times 10^8$	
	200 μg/ml	190 μg	$1\ 69 \times 10^8$	51
Glucose 1%	—	—	$2\ 94 \times 10^8$	
K_2HPO_4 0 2%	200 μg/ml	53 μg	$2\ 38 \times 10^8$	81
K_2HPO_4 0 2% $MgSO_4 7H_2O$ 0 01%	— 200 μg/ml	— 27 μg	$3\ 26 \times 10^8$ $2\ 94 \times 10^8$	90

as 2,4-dinitrophenol (10^{-4} M) and sodium azide (10^{-2}M) inhibited the accumulation, while they did not inhibit the oxidation of glucose by the resting cells and, moreover, promoted it at these concentrations

The next experiment was carried out to clarify whether the bactericidal action of oxytetracycline was strengthened in such a condition in which the accumulation of oxytetracycline was greatly promoted The incubation conditions and the results are given in Table 2 Viable cells were counted by the usual plate culture method As shown, bactericidal action of oxytetracycline was greatest in the presence of glucose, K_2HPO_4 and $MgSO_4$ at 30° C From these results, it is assumed that permeation and accumulation of oxytetracycline in the cell are relevant to the bactericidal action of oxytetracycline and are dependent on the energy-yielding system If supply of energy is necessary for the entry and accumulation of oxytetracycline, it is curious that bacteria take antibiotics into the cells using energy Perhaps bacteria can absorb the antibiotics at random since they cannot discriminate between such antibiotics and a certain nutrient as in the case of amino-acids and their analogues Recently, Hancock has reported the decreased uptake of streptomycin by the cells in the conditions such as anaerobiosis and presence of carbon monoxide[1]

VIROLOGY

Isolation of Louping ill Virus from the Red Grouse

WILD birds play an important part in the build-up and dissemination of some arboviruses[1] In the sub-group, the tick-borne encephalitis complex, evidence has been obtained from the U S S R [2], Czechoslovakia[3] and Holland[4] that some avian species are infected in Nature or can be infected with members of this group We report here the isolation from the red grouse (*Lagopus scoticus*) of louping ill virus, one of the members of the tick-borne complex, together with the results of some preliminary experiments on the susceptibility of this species to infection with louping ill virus

In June 1962 we examined a red grouse which had been found moribund on a hill in Morayshire In the course of serological investigations it was found to have a hæmagglutination inhibiting antibody titre of 1 80 against 4 units of louping ill virus antigen, and virus (*GRA*) was recovered from a 10 per cent brain emulsion in saline inoculated intracerebrally into suckling mice No virus was recovered from liver, spleen or lung During the period August–October 1962 we examined blood samples from 181 grouse killed over three areas in North Scotland —Speyside around Grantown-on-Spey, Morayshire, Braemar area, Aberdeenshire, and east Sutherland Louping ill is known to be endemic in parts of the first and last of these areas All the samples were from shot birds and blood was collected on filter paper strips The eluates were tested against 4 units of antigen for hæmagglutination inhibiting antibody The results are shown in Table 1

Table 1 HÆMAGGLUTINATION INHIBITING TITRES OF 181 RED GROUSE AGAINST LOUPING ILL VIRUS ANTIGEN

Area	No examined	Positive > 1 10	Negative	Reciprocal antibody titres 10–40	40–80	80–160
Speyside	88	10	78	7	2	1
Braemar	47	3	44	3	0	0
Sutherland	46	4	42	3	1	0

Some of the birds from the Speyside group were sent to the laboratory and virus (*GRB*) was isolated from the brain of one bird (hæmagglutination inhibiting titre 1 80) Both viruses isolated were bile-sensitive

The results of serological tests with these two isolates *GRA* and *GRB* in comparison with the mouse adapted (limb) strain of louping ill are shown in Table 2 We have failed so far to produce a hæmagglutinating antigen from one of them (*GRB*) by standard methods[5]

Table 2 SEROLOGICAL COMPARISON OF VIRUSES *GRA* AND *GRB* WITH LIMB STRAIN OF LOUPING ILL

Serum*	Virus	Hæmagglutination inhibiting	C F (fixation area)†	Neutralization Suckling mouse	Plaque	Metabolic inhibition
Limb	Limb	640	64/32	●	+	+
GRB	Limb	640	64/32	±	+	+
Limb	*GRB*	●	128/64	+	●	+
GRB	*GRB*	●	128/64	●	●	+
Limb	*GRA*	320	32/64	+	●	+
GRB	*GRA*	160	64/32	+	●	+

* Antisera made by inoculation of sheep with mouse brain virus suspension

† Highest dilution of serum fixing complement with any dilution of antigen/highest dilution of antigen reacting with any dilution of serum

Two grouse *X* and *Y*, one a wild bird, the other hatched in captivity and maintained at the Nature Conservancy Unit of Grouse and Moorland Ecology, Blackhall, Banchory, Kincardineshire, were made available to us by Dr D Jenkins, Natural History Department, Marischal College, Aberdeen, for experimental purposes A persistent viræmia developed in both those birds inoculated with the standard limb strain and they died within 8 days of inoculation (Table 3)

Table 3 INFECTION OF TWO RED GROUSE WITH LOUPING ILL VIRUS

	Grouse *X*		Grouse *Y*	
Pre-inoculation hæmagglutination inhibiting titre	Nil		Nil	
Subcutaneous inoculation dose of louping ill (limb)	25,000 mouse LD_{50}		2,500 mouse LD_{50}	
Post-inoculation blood samples (h)	Virus isolated	Hæmagglutination inhibiting titre	Virus isolated	Hæmagglutination inhibiting titre
7	+	–	+	–
31	+	–	+	–
79	+	1 10	+	1 80
168	Died		+	1 80
192			Died	

At death, grouse *Y* had 3×10^5 mouse LD_{50} virus/g liver, 3×10^5 mouse LD_{50} virus/g spleen, and 3×10^6 mouse LD_{50} virus/g brain tissue Histological sections of the brain examined showed marked congestion of the blood vessels but no obvious damage to nerve cells

We conclude that the red grouse can harbour louping ill virus in Nature, that viræmia sometimes occurs and in some circumstances the infection can be lethal to this species

These strains are held by Dr C. E Gordon Smith, Arbor Virus Research Unit, London School of Hygiene and Tropical Medicine.

PSYCHOLOGY

Effects of Field Brightness on an Induced Negative After-image Phenomenon

If a coloured stimulus, a white stimulus, and relative absence of stimulus are repeatedly presented in that order for 0 017, 0 10 and 0 083 sec respectively, there are values of stimuli brightness at which only the complement of the coloured stimulus is perceived This effect, first reported by Bidwell in 1897[1], has facilitated investigations of after-images, the decision as to which of two complementary colours is seen is more accurately made than are decisions as to the colour, intensity, or duration of after-images The study of induced negative after-images is of interest, as these phenomena depend on the relation between excitatory and inhibitory retinal reaction and may be used in physiological and pharmacological studies

In 1947 Lehmann[2] devised apparatus by means of which the brightness of the coloured stimulus was maintained at a fraction of that of the white stimulus and the effective illumination below which only the coloured stimulus and above which only its complement was seen Both Lehmann[2] and Kaplan[3], who used somewhat similar apparatus, determined that this threshold could be altered by pharmacological agents The equipment used in these investigations permitted the definition of only one set of brightness values of coloured and white stimuli at which reversal of colour perception occurs Keeler[4] constructed apparatus that would permit independent control of the brightness of the coloured and white stimuli and determined the curve of brightness of coloured versus brightness of white stimuli at which colour reversal occurs (A typical such curve is shown in Fig 1 as 'brightness of field' = 1/2 white stimulus)

In all of the apparatus in the investigations noted, the coloured-white-'black' stimuli cycle was presented on a field the brightness of which was a function of the brightness of the white stimulus (As the white stimulus is presented half the time, effective field brightness is about half that of this stimulus) In this circumstance, a change in brightness of the white stimulus changes field brightness which, in turn, alters the reactivity of that part of the retina receiving the image of the stimuli cycle This might be empirically satisfactory for some purposes, but the presentation of the stimuli-cycle on a field of constant brightness would give additional information as to the relations between white and coloured stimulus required for reversal of colour perception

The independent control of field brightness was also desirable, as this would make it possible to maintain the coloured stimulus at a constant value and determine any effects of field brightness on the brightness of the white stimulus necessary for reversal of colour perception

The equipment which generates the stimulus sequence[4] consists essentially of a whirling episcotister with a 180° white segment, a 130° black segment, and a 30° aperture through which an opal-glass target may be seen The episcotister is illuminated from above, the intensity of this illumination determines the brightness of the white stimulus The coloured stimulus is produced by trans-illuminating the opal-glass target The black segment provides relative absence of stimulus An aperture smaller than the meiotic human pupil in the eyepiece prevents changes in the subject's pupillary diameter from affecting retinal illumination. This equipment was revised by interposing a white screen, illuminated from above, with a 1° central aperture between the eyepiece and the episcotister A diaphragm, between the screen-illuminant and the screen, controls field brightness The system, as seen from the eyepiece, consists of a 1° central area in which the coloured-white-'black' cycle is presented visualized on a 5° white field of independently controlled brightness

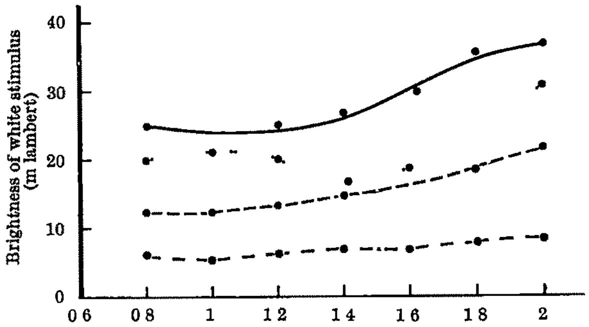

Fig 1 Effects of field brightness on the brightness of red and white stimuli at which, when the brightness of the red stimulus is held constant and that of the white stimulus increased, green rather than red is first perceived Red (625 mμ), white (3,000° K) and black stimuli are repeatedly presented in that order for 0 017, 0 10 and 0 083 sec respectively to the central 1° of a 5° white (3,000° K) field. ——, 50 m lamberts, , half-white stimulus, – – –, 25 m lamberts, – –, O

Some results obtained are presented in Fig 1, the curve generated when the brightness of the white stimulus determines that of the field is also included An orderly array of curves of brightness of the coloured stimulus versus the brightness of the white stimulus necessary for reversal of colour perception is generated With a coloured stimulus of constant brightness, an increase in field brightness requires an increase in the brightness of the white stimulus for reversal of colour perception The slope of the curves with constant field brightness is less than that in the situation where the white stimulus also determines the field This may be explained on the basis that, in this latter circumstance, an increase in the brightness of the coloured stimulus will necessitate an increase in the brightness of the white stimulus and thus, in field brightness which will require a yet further increase in the brightness of the white stimulus

The results shown are for one subject typical of six All determinations were made with a red (625 mμ) stimulus, the brightness of the white stimulus was increased until green rather than red was perceived Absolute values vary among observers and in the same observer over time, but the relations among stimuli and field brightness noted are consistent

Most significantly, these data indicate that the device may be quite responsive to changes in the sensitivity of the part of the retina which receives the image of the field, such changes would be equivalent to changes in field illumination This is crucial in the interpretation of drug-induced changes in the colour reversal threshold Even when the stimuli cycle is presented to the fovea (and thus to the cone-based systems) changes in the reactivity of the peri-foveal region (and thus rod-based systems) may alter the endpoint

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, October 14

University of London (at the Postgraduate Medical School of London, Du Cane Road, London, W.12), at 4 p m —Dr Brian Ackner "Disorders of Personality" *

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Patents and British Industry Today", opened by Mr P Ford

Institution of Mechanical Engineers, Manipulative and Mechanical Handling Machinery Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Modern Advances in the Design and Use of Automatic Vending Machines"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 6 p m —Mr Eric Shipton, C.B E "Patagonian Adventure" (colour films with commentary)

Society of Chemical Industry, London Section (joint meeting with the Surface Activity Group, at 14 Belgrave Square, London, S W 1), at 6 p m —Dr J M Corkill "The Structure of Thin Detergent Films"

Plastics Institute, Engineering Sub-Group (at "The Ring", Blackfriars Road, London, S.E 1), at 6 30 p m —Mr. P J Gough "Toolmaking by Spark and Electrochemical Erosion".

Tuesday, October 15

The Wellcome Trust (in the Wellcome Historical Medical Library, The Wellcome Building, Euston Road, London, N W 1), at 1 p m —Dr Edwin Clarke "Hippocrates as a Clinician" * (First of twelve lectures on "The History of Medicine" Further lectures on October 17, 22, 24, 29, 31, November 5, 7, 12, 14, 19 and 21)

University of London (at Queen Mary College, Mile End Road, London, E 1), at 5 p m —Prof M F Hawthorne (University of California) "Recent Advances in the Chemistry of the Higher Hydrides of Boron" (Further lecture on October 17)*

University of London (at the Institute of Education, Malet Street, London, W C 1), at 5 15 p m —Dr D M Lee "Perception, Intuition and Insight".*

Institution of Civil Engineers (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Mr P S A Berridge "Factors Governing the Choice between Repairing, Strengthening and Reconstructing Railway Girder Bridges".

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W C 2), at 5 30 p m —Dr J R Mortlock "Computers for Engineers" (Chairman's Address)

Royal Institution (at 21 Albemarle Street, London, W 1), at 5 30 p m —Sir Lawrence Bragg, F R S "Electrical Charges and Electrical Currents" (Afternoon Lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties Further lectures on October 16, 22 and 23)

University of London (in the Physiology Lecture Theatre, Royal Free Hospital School of Medicine, Hunter Street, Brunswick Square, London, W C 1), at 5 30 p m —Prof P K Anokhin (Moscow) "New Data of the Specific Character of Ascending Activation on Brain Cortex" *

Institution of Mechanical Engineers, Applied Mechanics and Steam Plant Group (at Rugby College of Engineering Technology, Rugby), at 6 30 p m —Mr M B Coyle and Mr S J Watson. "The Fatigue Strength of Turbine Shafts with Shrunk-On Discs".

Wednesday, October 16

University of London (at the Postgraduate Medical School of London, Du Cane Road, London, W 12), at 2 p m —Dr J R Hobbs "Immunoglobulins and their Paraproteins" *

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S W 7), at 4 p m —Annual General Meeting Mr D G King-Hele "Theories About the Shape of the Earth" (Third Duke of Edinburgh's Lecture).

Royal Society of Medicine, Comparative Medicine Section (at 1 Wimpole Street, London, W 1), at 5 p m —Mr K C Sellers "Breeding for Feeding, Present and Future Food Animal Populations" (Presidential Address)

University of London (in the Physiology Lecture Theatre, Royal Free Hospital School of Medicine, Hunter Street, Brunswick Square, London, W C 1), at 5 30 p m —Prof P K Anokhin (Moscow) "New Information on the Mechanisms of the Conditioned Reflex" *

British Coal Utilisation Research Association (at the Institution of Civil Engineers, Great George Street, London, S W 1), at 5 30 p m —Dr D T A Townend, C B E "Some Reflections on Combustion" (Twelfth Coal Science Lecture)

Society for Analytical Chemistry, Microchemistry Group (at "The Feathers", Tudor Street, London, E C 4), at 6 30 p m —Discussion Meeting on "The Determination of Boron" introduced by Dr H J Cluley and Mr M R Hayes

Thursday, October 17

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr T A Quilliam "Information from the Skin—How is Vibration Detected?" *

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p m —Dr M J Jaycock and Dr R H Ottewill "Adsorption of Ionic Surface Active Agents by Charged Solids", Prof I N Plaksin and Mr R Sh Shafeev "Influence of Surface Properties of Sulphide Minerals on Adsorption of Flotation Reagents", Prof R Higgins and Dr T J B Jones "Viscosity Characteristics of Rhodesian Copper Smelting Slags"

Linnean Society of London (at Burlington House, Piccadilly, London, W 1), at 5 p m —Miss A G C Grandison "Herpetological Travels in Nigeria", Dr D C Smith "Some Recent Studies in the Biology of Lichens"

University of London (at Goldsmiths' College, New Cross, London, S E 14), at 5 p m —Prof. Herbert Dingle "The Impact of Science in the Humanities" *

Institution of Civil Engineers (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Informal Discussion on "Recent Developments in Piling Theory"

University of London (in the Beveridge Hall, Senate House, London, W C 1), at 5 30 p m —Sir Charles Dodds, F R S "Stilbœstrol and After" * (First of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

British Institute of Radiology (at 32 Welbeck Street, London, W 1), at 6 p m —Discussion Group meeting on "X-Ray Departments and the Ministry of Health" 8 p m —Prof C B Allsopp "Nothing New?" (Presidential Address)

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S W 1), at 6 p m —Dr J D Watt "The Composition and Pozzolanic Properties of Pulverised Fuel Ash"

Royal Institute of Chemistry, London Section (joint meeting with the Brighton College of Technology Chemical Society, at the College of Technology, Lewes Road, Brighton), at 7 p m —Prof R N Haszeldine "Carbanions to Carbenes"

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W 1), at 7 30 p m —Dr Charles Wilcocks Presidential Address

Friday, October 18

Biochemical Society (in the Department of Physiology and Biochemistry, The University, Southampton), at 9 15 a m —Colloquium on "Comparative Biochemistry and Physiology" 2 15 p m —Scientific Papers

University of London (in the Physiology Lecture Theatre, Royal Free Hospital School of Medicine, Hunter Street, Brunswick Square, London, W C 1), at 5 30 p m —Prof P K Anokhin (Moscow) "Neurophysiological Bases of the Therapeutic Action of Anæsthetic and Psychotropic Drugs" *

Occam Society (at the Northampton College of Advanced Technology, St John Street, London, E C 1), at 6 15 p m —Discussion on "The Philosophical Importance of the Unconscious" opened by Mr Paul de Berker

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Prof S K Runcorn "How the Continents Drift"

Friday, October 18—Saturday, October 19

Faculty of Radiologists, Radiological Section of the Royal Society of Medicine, and the British Institute of Radiology (in the Barnes and West Halls, Royal Society of Medicine, 1 Wimpole Street, London, W 1 (Radiodiagnostic Meetings), and Cowdray Hall, Royal College of Nursing, 1a Henrietta Place, London, W 1 (Radiotherapy Meetings))—Meeting on "The Planning of Diagnostic X-ray and Radiotherapy Departments"

Saturday, October 19

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Dr Eva Crane "Dances and other Forms of Communication Between Bees" *

Monday, October 21

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S W 1), at 5 30 p m —Dr J Metivier and Dr B J Heywood "Vamidothion—a New Systemic Insecticide"

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W C 2), at 6 30 p m —Mr R C Foss "Feedback" (Chairman's Address)

Royal Geographical Society (at 1 Kensington Gore, London, S W 7)• at 8 15 p m —Mr Tom Harrisson "Inside Borneo"

Monday, October 21—Tuesday, October 22

Powder Metallurgy Joint Group of the Iron and Steel Institute and the Institute of Metals (at the Royal Commonwealth Society, Craven Street, London, W C 2), at 11 15 a m on Monday and 10 a m on Tuesday—Symposium on "Residual Porosity in Powder Metallurgy"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Senior Lecturer (with an honours degree in mathematics and preferably some lecturing or industrial experience) in Mathematics—The Director of Education, The Polytechnic, 309 Regent Street, London, W 1 (October 18)

Electronic Computer Operator (education to G C E "A" level standard in mathematics, and preferably previous experience on digital computers), to be concerned with the preparation and running of programmes on the KDF9 computer which is to be installed in the College later this year—The Secretary, Royal College of Advanced Technology, Salford 5, Lancs, quoting Ref MA/11 (October 21)

Assistant Lecturer (preferably with an interest in one of the following fields taxonomy, ecology, plant physiology or microbiology (bacteriology)) in Botany—The Secretary, Birkbeck College (University of London), Malet Street London, W C 1 (October 28)

Research Assistant (with experience in embryology and/or biophysics) in the Department of Zoology, for work on the effect of drugs on the uptake and distribution of water in the developing embryo—Dr P H Tuft, Department of Zoology, University of Edinburgh, West Mains Road, Edinburgh (October 31)

Senior Lecturer, a Junior Lecturer, and a Graduate Assistant in the Department of Electrical Engineering, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, October 31)

Lecturer in Veterinary Physiology at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, November 1)

Scientific Officer/Senior Scientific Officer (with a good honours degree in physiology or biochemistry, and preferably an additional veterinary qualification and research experience in the field of animal metabolism) in the Physiology Department—The Secretary, Rowett Research Institute, Bucksburn, Aberdeen (November 1)

Lecturer (preferably competent to lecture in logic, including traditional logic) in Philosophy at the University of Sydney, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, November 5)

Lecturer and an Assistant Lecturer (with research interests in the high energy physics field) in the Department of Physics—The Registrar, The University, Manchester 13 (November 15)

Lecturer or Assistant Lecturer (preferably with interests in the field of cytology or cytogenetics) in Botany—The Secretary, The University, Aberdeen (November 18)

Chair of Medical Microbiology at St Thomas's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W C 1 (November 20)

Senior Lecturer (with a Ph D in physics or equivalent qualification, and preferably some teaching experience) in Physics or Theoretical Physics in the School of General Studies, Australian National University—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (London and Australia, November 25)

Assistant Professor (with a Ph D or equivalent in animal physiology, and preferably a minor in biochemistry) of Animal Physiology, for duties which include fundamental and applied research with farm and laboratory animals with emphasis on environmental physiology, teaching, and limited extension work—Head, Department of Animal Science, University of Alberta, Edmonton, Alberta, Canada (November 30)

Chair of Electronics—The Secretary, The Queen's University, Belfast, Northern Ireland (November 30)

Hospital Microbiologist (medical graduate with suitable experience in microbiology), to assist the Director (Prof N F Stanley) in the administration of the routine laboratory and clinical services of the Hospital Department of Microbiology, to act in the absence of the Director, and to carry out special investigations from time to time—The Administrator, Royal Perth Hospital, Perth, Western Australia (November 30)

Lecturers or Senior Lecturers (2) in Psychology at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, November 30)

Senior Lecturer in Statistics at the University of Melbourne—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, November 30)

Biochemist (with a first- or second-class honours degree in chemistry, or veterinary qualifications with additional specialization in biochemistry, and preferably experience of the application of modern biochemical techniques to the study of animal diseases), with the Government of Uganda, to work with members of the research staff in establishing modern biochemical techniques for research into adaptation and diseases of domestic livestock in Uganda—The Director of Recruitment, Department of Technical Co-operation, Eland House, Stag Place, Victoria, London, S W 1, quoting Ref RC 217/153/04/61

Executive Officer (male, preferably not under 30, and fully conversant with the technical aspects of medical laboratory practice and equipment), for work at the Medical Research Council's Central Store, Colindale Avenue, London, N W 9—Medical Research Council, 20 Park Crescent, London, W 1, quoting Ref E 10/29

Head (with good qualifications and experience) of the Science Department—The Headmaster, The School, Oundle, Peterborough, Northants

Post-doctoral Fellow (with a sound background in physical organic chemistry and/or modern analytical techniques) in Hæmoprotein Chemistry—Dr G R Schonbaum, Department of Biochemistry, University of Alberta, Edmonton, Alberta, Canada

Research Assistant (with a good honours degree in chemistry or physical chemistry (or a good G R I C), and preferably some research experience), for work on the cross-linking of high polymers in solution—Prof R H Peters, Department of Polymer and Fibre Science, The Manchester College of Science and Technology, Sackville Street, Manchester 1

Research Fellow in the Department of Anatomy, to study the physiology of reproduction and in particular to investigate the control of fertility in primates and lower mammals—The Assistant Registrar, The Medical School, The University, Birmingham 15

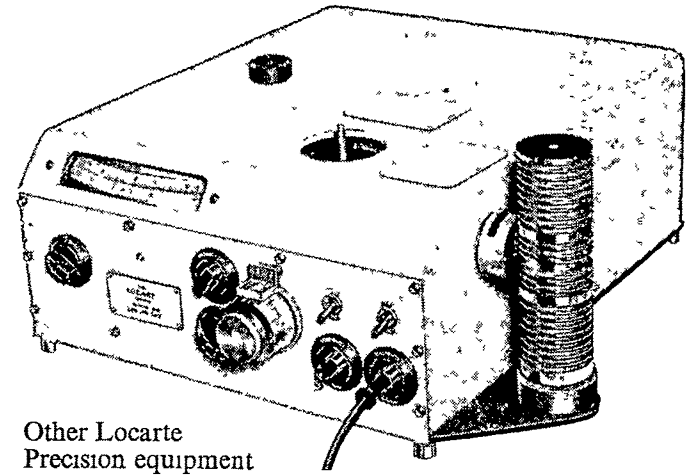
LOCARTE Fluorimeter

Excitation wavelengths commencing at 240mμ



Other Locarte Precision equipment includes: Fraction Collectors, H V Electrophoresis, U V Handlamps, Recording Densitometers, Desalters, Column Scanners, Pipette Washers, Amino Acid Analysers.

The Locarte Company

24 Emperors Gate, London, S.W.7 Fre 1712

In Laboratories throughout the world the Locarte Fluorimeter is saving time while providing unparalleled results. Important work demands precision. An extensive range of filters is available.

With an instrument so sensitive that monochromatic filter can be used on both primary and secondary sides many laboratories have extended their sphere of work With an instrument so fast in operation your costs are reduced

RAPID measurement of fluorescence (solution or filter paper).

SENSITIVITY: Minimum cuvette 'blank' allows full use of 13 stage photomultiplier and allows estimations well below .001 μg/ml. Quinine Sulphate; 001 μg/ml. Serotonin (measuring the fluorescence in the Ultra Violet at 335 mμ.) & 1 μg of Cortisol on filter paper.

STABILITY: ensured by fully regulated Special Mercury or Zinc Arc Lamp.

REPRODUCIBILITY SPEED AND ACCURACY in all your fluorometric estimations

[Consider: *isn't this just plain common sense?*]

200 years ago life assurance as we know it began—with the Society that became known as the 'Old Equitable', the oldest mutual life office in the world

Unswervingly through the years, the 'Old Equitable' has stuck to its principles, of no shareholders, of paying no commission for the introduction of business and of sharing its profits among members Today, as helpful as ever and of great financial strength, the 'Old Equitable' provides life assurance for its members at cost price

For instance a quarterly payment of £26 7 6 secures a man of 34 an endowment assurance of £2,500, sharing in major profits and payable shortly before he is 60 or at his earlier death Those who took out such policies 25 years ago are receiving £4,315 this year

For more about 'Old Equitable' assurances, please fill in this coupon

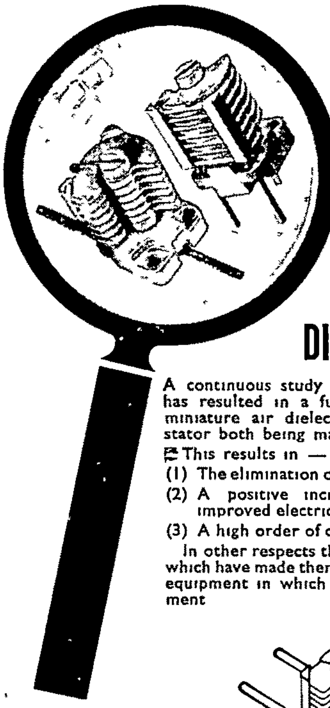
OXLEY DEVELOPMENTS CO. LTD.



OXLEY SUBMINIATURE AIR DIELECTRIC TRIMMERS

A continuous study in the laboratory and in the field has resulted in a further development in Oxley subminiature air dielectric trimmers, the rotor and the stator both being made of solid metal

This results in —

(1) The elimination of practically all soldered joints
(2) A positive increase in mechanical rigidity and improved electrical stability
(3) A high order of consistency in capacity

In other respects the trimmers retain all those facilities which have made them the inevitable choice of professional equipment in which reliability is the dominant requirement

APPOINTMENTS VACANT

(SECOND ADVERTISEMENT)

UNIVERSITY OF EDINBURGH

DEPARTMENT OF ZOOLOGY

Research Assistant, with experience in Embryology and/or Biophysics, is required by the Department of Zoology for work on the effect of drugs on the uptake and distribution of water in the developing embryo The appointment will be for three years in the first instance Salary within the range of £1,000 to £1,150 per annum, plus F S S U

Applications (three copies), with curriculum vitae and the names of two referees, should be sent to Dr P H Tuft, Department of Zoology, University of Edinburgh, West Mains Road, Edinburgh, not later than October 31, 1963

CHARLES H STEWART,
Secretary to the University

PILKINGTON BROTHERS LIMITED
Glass Manufacturers, require a

PHYSICIST

age between 25 to 30 years, at their Research Laboratories to carry out basic research work covering theoretical and experimental investigations of heat transfer and model studies of viscous and non-viscous flow in glass-making processes

The work involves design and analysis of experiments at small-scale laboratory and pilot plant level

A good honours degree in Physics is essential with some experience of university or industrial research

The salary is in a range which can rise to £2,000 per annum

Applications should be made, quoting RES/J 3, to L P Laidlaw

GROUP STAFF DEPARTMENT,
Pilkington Brothers Limited,
Grove Street, St Helens, Lancashire

MANCHESTER EDUCATION COMMITTEE

JOHN DALTON COLLEGE OF TECHNOLOGY

METALLURGY DEPARTMENT

COLLEGE OF SCIENCE AND TECHNOLOGY

Applications are invited for the post of either Senior Lecturer or Lecturer in the Department of Metallurgy of the John Dalton College of Technology This Department is at present housed in the Manchester College of Science and Technology, and is running a Sandwich Course in Metallurgy leading to the Higher National Diploma and to Associateship of the Institution of Metallurgists There is also in operation a day-release course for the Higher National Certificate in Metallurgy These courses are expected to develop when the department moves into the new John Dalton College of Technology in September, 1964 Preference will be given to candidates who are qualified to teach Physical Metallurgy and X-ray Metallography Experience specifically in the field of physical metallurgy of the refractory and reactive metals would be an advantage Salary in accordance with the Burnham Further Education Report, 1961, as amended, viz Lecturer, £1,670 to £1,895 per annum, or Senior Lecturer, £1,895 to £2,115 per annum

Forms of application, etc (s a e), from the Chief Education Officer, P O Box 480, Deansgate, Manchester, 3, returnable by October 21, 1963 Please quote reference number FE/81

REPUBLIC OF IRELAND

THE IRISH MEAT RESEARCH INSTITUTE

invites applications for the post of

DIRECTOR

to take charge of the Meat Research Unit which it proposes to establish in Dublin. The duties of this post will entail responsibility for research on the needs of the meat industry in Ireland with particular emphasis on processing, canning and packaging

Qualifications Honours degree in Chemistry or Bacteriology, with a knowledge of each or equivalent

The candidate most likely to be appointed would have an established reputation in Technological Developmental Research

It is hoped that the successful candidate will be able to take up appointment from the beginning of 1964 , he will be expected to take an active part in the establishment of the new Institute and the planning of its research programme

Commencing salary will be in the range £2,500 to £3,000 Superannuation will apply

Intending candidates are invited to submit full personal details with copies of publications, particulars of experience, etc , to The Secretary, The Irish Meat Research Institute, 7 Gardiner Row, Dublin, 1, not later than October 31, 1963

UNIVERSITY OF CANTERBURY

NEW ZEALAND

LECTURER IN ELECTRICAL ENGINEERING

Applications are invited for the abovementioned post The appointee will be expected to devote his main attention either to the Electronics side or to the Power side of Electrical Engineering and he should either have or be prepared to acquire a basic knowledge of Nuclear Engineering and Measurements The salary attached to the position will be at the rate of £1,250 per annum rising by annual increments of £75 to £1,700 per annum and will commence at a rate in accordance with qualifications and experience Approved fares to Christchurch will be allowed for an appointee, his wife and children In addition, actual removal expenses will be allowed within certain limits

Further particulars and information as to the method of application are available from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close in New Zealand and London on November 1, 1963

NATIONAL COLLEGE OF FOOD TECHNOLOGY

ST GEORGE'S AVENUE, WEYBRIDGE, SURREY

Principal J D Mounfield, M Sc Tech , Ph D , F R I C

Applications are invited from graduates in microbiology or in chemistry/biochemistry with training or experience in microbiology, for a teaching post at the College Facilities for research are available Appointments may be made at Lecturer or Assistant Lecturer level Salary scales Lecturer, £1,670 by £45 to £1,895 per annum , Assistant Lecturer, £930 to £1,550 per annum Starting salary dependent on qualifications and experience

Application forms (obtainable from the College), should be sent to the Principal as soon as possible

---

SOUTH-EAST ESSEX TECHNICAL COLLEGE AND SCHOOL OF ART

LONGBRIDGE ROAD, DAGENHAM

Required in January Assistant Lecturer, Grade B, to teach Zoology to G C E "A" level and B Sc General Degree level Candidates should have a good honours degree in zoology, preferably with some industrial and/or teaching experience Salary scale £1,050 to £1,670 per annum (good honours graduates), plus London Allowance of £45 or £60 per annum Higher scales possible, depending on length of training Increments above the scale minimum allowed for War/National Service, previous teaching and relevant industrial experience Assistance towards the cost of removal expenses will be considered

Further particulars and application form from the Principal

UNIVERSITY OF THE WITWATERSRAND JOHANNESBURG

DEPARTMENT OF ELECTRICAL ENGINEERING

VACANCIES SENIOR LECTURER JUNIOR LECTURER GRADUATE ASSISTANT

Applications are invited for the above three vacant posts, two of which are new posts The Department of Electrical Engineering desires to strengthen its teaching and research activities in the general field of microwave engineering, and also in the field of high voltage and dielectrics study and research Applicants are invited to state for which post they wish to be considered Duties are to be assumed on January 1, 1964, or as soon as possible thereafter The salary scales of the various posts are as follows Senior Lecturer, R 3 420 by R 120 to R 4,500 (£1,710 by £60 to £2,250) , Junior Lecturer, R 1,740 by R 120 to R 2,100 (£870 by £60 to £1,050) , Graduate Assistant, R 804 fixed (£402) In addition an annual vacation bonus is payable in the case of the Senior Lectureship and the Junior Lectureship

Intending applicants are advised to obtain a copy of the information sheet relating to these vacancies from the Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close in South Africa and London on October 31, 1963

UNIVERSITY OF ST ANDREWS

Workshop Technician required for the Department of Physics, St Salvator's College, St Andrews University, St Andrews Work is mainly on research projects requiring high standards, advanced technology, e g , cryogenic and laser, with no repetition work Salary scale £540 to £745 per annum, starting salary according to experience Supplements of about £30 to £50 per annum for qualifications Possibility of advancement to higher grades in a rapidly growing department

Applications, with testimonials and names of two referees, should be sent by November 15, 1963, to the Secretary of the University, College Gate, St Andrews

---

AGRICULTURAL RESEARCH COUNCIL

Geneticist to work on developmental genetics and gene action in *Drosophila*, required for the staff of the Poultry Research Centre, Edinburgh Good honours degree essential Appointment as Scientific Officer in scale £791 to £1,309 according to experience F S S U

Applications, with names of three referees, to Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh, 9

RESEARCH CHEMICAL ENGINEER

Monsanto Chemicals Limited require a Research Chemical Engineer with an interest in reaction kinetics to work on chemical engineering aspects of high-pressure polymerization reactions This work will be carried out in our research facilities at Fawley, Hampshire, on the edge of the New Forest

Applicants should have a good honours degree in chemical engineering with postgraduate or industrial research experience

Good starting salary and career prospects, non-contributory pension scheme

Please send applications, giving details of age, education, and previous experience, to

The Staff Officer (DL 252), Monsanto Chemicals Ltd,
Monsanto House, 10-18 Victoria Street, London, S.W.1.

RESEARCH CHEMIST

Applications are invited from men aged 25 to 30 years, having a degree in physical chemistry with postgraduate or industrial research experience, for a position in our modern laboratory at Fawley, near Southampton

The work will comprise a laboratory-scale study of the kinetics of polymerization and copolymerization reactions at high pressures Applicants should have a sound background of reaction kinetics and a mechanical bent would be helpful Familiarity with the various methods of polymer characterization would be a useful qualification

Good starting salary and career prospects, non-contributory pension scheme

Please send applications, giving details of age, education, and previous experience, to·

The Staff Officer (DL 253), Monsanto Chemicals Limited,
Monsanto House, 10-18 Victoria Street, London, S.W.1.

BIOCHEMIST

An opportunity occurs for a Biochemist to lead a research group with a Company which is one of the leading manufacturers in Canada

The work is concerned generally with the biochemistry of plants during growth and subsequent processes

The successful applicant will probably be between 25 and 35 and have a higher degree in organic or biochemistry with some interest in botany He should have a good background in natural products chemistry, some experience in leading research, and a potential to command a high salary Starting salary envisaged is not less than $8,000 per annum, with other benefits, re-location expenses, etc

Preliminary interviews will be arranged in England No approach will be made to present employers without the applicant's prior knowledge and consent

Applicants should send a brief account of their qualifications and experience to Box No 728, T G Scott and Son, Ltd, 1 Clement's Inn, London, W C 2

AUSTRALIA
THE UNIVERSITY OF NEW SOUTH WALES
SYDNEY

invites applications for appointment to the positions of

SENIOR LECTURER/LECTURER (2 positions)
and
LECTURER
SCHOOL OF MATHEMATICS

Salary Senior Lecturer, £A2,755 range £A3,255 per annum Lecturer, £A1,905 range £A2,605 per annum Commencing salary according to qualifications and experience Applicants must hold at least an honours degree of high standing in mathematics or have equivalent qualifications and be able to produce evidence of strong research interests and experience For appointment as Senior Lecturer a higher degree is essential The School, which is organized into four departments, has active research interests in a number of fields of pure mathematics, applied mathematics and mathematical statistics These include number theory, group theory, analysis, integral transforms, general relativity, reactor theory, fluid flow, statistical mechanics, superconductivity, theoretical nuclear physics, numerical analysis, stochastic processes, experimental design and discrete distribution theory (Professor of Pure Mathematics G Szekeres, Professor of Applied Mathematics J M Blatt, Professor of Mathematics G Bosson, Associate Professor of Mathematical Statistics J B Douglas) The successful applicants will lecture in their own speciality but will also participate in the general teaching programme of mathematics in science and engineering courses

Details of conditions of appointment may be obtained from the Agent-General for New South Wales, 56-57 Strand, London, W C 2, with whom four copies of applications and names of two referees should be lodged before November 15, 1963, and a copy of the application should be forwarded, by air mail, to the Appointments Section, the University of New South Wales, Box 1, Post Office, Kensington, New South Wales

---

UNIVERSITY OF SHEFFIELD

Applications are invited for two posts as Research Assistant to take part in programmes designed to study (1) human chromosome abnormality and associated disorder, and (2) chromosome behaviour in normal and abnormal karyotypes Suitable for graduates with a first degree in the Biological Sciences or Chemistry Initial salary up to £1,100 per annum, according to qualifications and experience

Please apply to the Secretary, Genetics Department, the University, Sheffield, 10, giving full details of qualifications and experience and the names of two referees

---

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF ANATOMY
RESEARCH FELLOW IN ENDOCRINOLOGY

Applications are invited for a Research Fellowship in the Department of Anatomy (Professor Sir Solly Zuckerman, C B, F R S) to study the influence of environmental and other factors on seasonal changes in the ferret The salary will depend on qualifications and experience and will include F S S U and family allowance benefits

Further particulars may be obtained from Dr W P Dallas Ross, the Department of Anatomy, the Medical School, Birmingham, 15, to whom applications, naming two referees, should be sent as soon as possible

---

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF ANATOMY
RESEARCH FELLOWSHIP IN THE PHYSIOLOGY OF REPRODUCTION

Applications are invited for a Research Fellowship in the Department of Anatomy (Professor Sir Solly Zuckerman, C B, F R S) to study the physiology of reproduction and in particular to investigate the control of fertility in primates and lower mammals The salary will be determined according to qualifications and experience F S S U and family allowance will be paid Initially the appointment will be for a period of two or three years, which may be extended

Further particulars may be obtained from the Assistant Registrar, the Medical School, Birmingham, 15, to whom applications, naming two referees, should be sent as soon as possible

---

SENIOR TECHNICIAN, REQUIRED FOR work on the isolation and structure of proteins in the Plant Biochemistry Section of Twyford Laboratories Ltd (subsidiary of Arthur Guinness Son & Co Ltd) Opportunity for collaboration in original research Excellent conditions, contributory pension scheme, salary according to age and experience —Apply in writing to the Secretary, Twyford Laboratories Ltd, Twyford Abbey Road, London, N W 10

Graduate PHYSICIST

(male or female)

required at the new laboratory of the Gas Council Research Station, Watson House, Peterborough Road, FULHAM, S W 6

The project includes fundamental studies of the aerodynamics of combustion systems and of the combustion properties of new gases This involves the use of visualization techniques, the use of flow models and the development of new measurement techniques of velocities and temperatures in high temperature gas streams

Starting salary according to age, qualifications and experience will be within the range of £785 to £955 per annum

The successful applicant will be required to join the Staff Pension Scheme

Applications, stating age and giving full details of training and experience, should be sent to the Appointments Officer, North Thames Gas Board, 30 Kensington Church Street, W 8, quoting reference NE/1660

OLDCHURCH HOSPITAL

ROMFORD, ESSEX

(651 beds)

RADIOTHERAPY DEPARTMENT

Senior Technician, or Technician required for the above Department Duties include Physics Workshop, Isotope Laboratory, Radium and Mould Room work Instrument or physics workshop experience essential Salary £570 to £710 per annum Senior grade £710 to £905 would be applicable to suitably qualified person London Weighting Allowance payable

Applications, quoting Ref 20/98, giving full details, including age and experience, together with names of two referees, and/or copies of testimonials to the Group Secretary at the Hospital

---

ADVANCED SCHOOL OF AUTOMOBILE ENGINEERING

CRANFIELD

Applications are invited for appointment as Senior Research Fellow to carry out research under the sponsorship of the Nuffield Foundation into vibration in relation to vehicle comfort Candidates should possess an honours degree and the person appointed will be permitted to submit his work for a higher degree The post would be suitable for a control engineer or physiologist, with appropriate experience Salary according to qualifications and experience in range £1,275 to £1,600 per annum, with F S S U and family allowance The appointment is initially for a period of three years

Applications to the Registrar, The College of Aeronautics, Cranfield, Bletchley, Bucks

---

UNIVERSITY OF ST ANDREWS

Applications are invited for a Post-Doctoral Research Fellowship awarded by the Department of Scientific and Industrial Research and tenable in the School of Natural Philosophy, St Salvator's College, St Andrews The work will be on " Relaxation Time Measurements in Solids by Spin-Echo Techniques " and is part of an expanded programme of research in the field of nuclear magnetic resonance linked with the existing broad-line programme There will be a considerable expansion in all research facilities when a new physics building is occupied in 1965 The appointment will be for a maximum of three years from a date to be arranged and the salary will be in the range £1,000 to £1,100 per annum, with F S S U benefits where appropriate

Applications should be sent as soon as possible, and preferably not later than October 31, 1963, to the Secretary of the University, St Andrews, Scotland, from whom further details may be obtained

---

COLLEGE OF ADVANCED TECHNOLOGY

BIRMINGHAM

LECTURER IN PRODUCTION ENGINEERING

Candidates should be able to cover subjects from Machine Tool Technology and Design, Metrology, Quality Control Tool Engineering, Methods Engineering, Metal Forming theory and practice, Applied Control Engineering including Numerical Control of Machine Tools, Precision Casting Salary scale £1,600 to £1,800 per annum according to qualifications and experience This scale is subject to revision following the reference of salaries in Universities and Colleges of Advanced Technology to the National Incomes Commission

Further particulars and forms of application from the Staff Officer, College of Advanced Technology, Gosta Green, Birmingham 4, to whom applications should be forwarded within fourteen days of this advertisement Please quote 10/63/6

STAFFORDSHIRE COUNTY COUNCIL EDUCATION COMMITTEE

STAFFORDSHIRE COLLEGE OF TECHNOLOGY

Principal R S Paradise, B Sc (Eng) Hons , M I Mech E , A M I Mar E

MATHEMATICS AND SCIENCE DEPARTMENT

Applications are invited for a post of Assistant Lecturer Grade " B," duties to commence on January 1, 1964 Candidates should have a University degree together with the ability to teach Physics to B Sc General Degree level, and to assist with the teaching of Mathematics or Chemistry

Participation in research will be encouraged, facilities and time are available

Salary in accordance with the Burnham Technical Scale for Assistant Lecturer Grade " B " = £830 to £1,760 per annum

In certain circumstances allowances will be made towards the cost of lodging and removal expenses The Authority also has a scheme whereby loans towards house purchase can be made with a repayment period of up to 25 years in approved cases

Forms of application and further particulars may be obtained by sending a stamped addressed foolscap envelope to the Director of Education (Staffing), County Education Offices, Stafford , completed applications to be returned direct to the Principal at the College by October 18, 1963

NEW ZEALAND

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH

Applications are invited for the undermentioned vacancy Vacancy B13/18/18/2758 Scientific Officer (Paleontologist) N Z Geological Survey, Lower Hutt Salary Up to £1,780 a year according to age and experience and further advancement is on scientific merit Qualifications desired B Sc (Hon) or M Sc with zoology and/or geology as leading subjects Duties To undertake research on the systematics and history of Tertiary molluscan fauna of New Zealand and thus to contribute to their use in stratigraphy Passages Fares for appointee and his wife and family, if married, will be paid Incidental expenses Up to £35 for a single man and £100 for a married man can be claimed to cover the cost of taking personal effects to New Zealand

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, S W 1, with whom applications will close on December 18, 1963 Please quote reference B13/18/18/2758 when inquiring

---

UNIVERSITY OF NOTTINGHAM

A vacancy exists at the School of Agriculture for a Technical Assistant in the Department of Agricultural Sciences to work on problems in Micro-Meteorology Duties will include installation and maintenance of instruments, collection of physical data relating to crop environment, and development of original instrumentation Preference given to applicants with H N C in physics, or equivalent qualifications, and experience in use of modern recording apparatus Appointment on one of the following scales £985 to £1,120 per annum, or £760 to £900 per annum, with supplement of £50 or £30 per annum for appropriate qualifications

Applications to the Secretary, School of Agriculture Sutton Bonington, Loughborough

---

YOUNG INFORMATION SCIENTIST

with good academic qualifications to undertake a variety of work, including abstracting, compiling bibliographies, answering technical inquiries and editing technical publications A broad scientific background is needed and some practical experience of instruments would be an advantage Starting salary up to £1,100 per annum, with good prospects

Apply, quoting reference AESM, to the Acting Director, R E Fischbacher, B Sc , A R C S T , A M I E E , BRITISH SCIENTIFIC INSTRUMENT RESEARCH ASSOCIATION, " Sira," South Hill, Chislehurst, Kent

---

ROYAL COLLEGE OF ADVANCED TECHNOLOGY

SALFORD

Applications are invited for a post of Laboratory Assistant from persons with experience of animal house maintenance and work in experimental physiology For candidates aged 21 years and over the salary will be on the scale £665 per annum to £730 per annum The post is superannuable

Applications, giving full particulars and the names and addresses of two referees, should be addressed to the Secretary, Royal College of Advanced Technology, Salford, 5, as soon as possible, quoting reference CH/13

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

(FACULTY OF TECHNOLOGY IN THE UNIVERSITY OF MANCHESTER)

Applications are invited for the following posts of Experimental Officers in the Department of Polymer and Fibre Science (a) One Experimental Officer to work in the field of spectrophotometry This involves the care of the Department's spectrophotometers and other optical measuring equipment The candidate will be expected to assist in research in the area of colour or fibre physics (b) One Experimental Officer to look after the polymer physics equipment and to assist in research work in this field Salary in the scale £880 by £40 to £1,200 Superannuation scheme Family allowances

Further particulars and forms of application may be obtained from the Registrar of the College, The Manchester College of Science and Technology, Sackville Street, Manchester, 1, to whom completed applications should be returned by Saturday, October 26, 1963

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

(FACULTY OF TECHNOLOGY IN THE UNIVERSITY OF MANCHESTER)

Applications are invited from graduates in physical science or technology for a Lectureship or Assistant Lectureship in the Department of Paper Science, with corresponding title and status in the University of Manchester Industrial and research experience is desirable, and candidates should be prepared to become interested in research in Paper Technology Some private consulting work is permitted Commencing salary will be determined according to experience in the scales : Lecturer, £1,250 to £60 by £1,670 by £80 to £2,150 Assistant Lecturer, £1,000 by £50 to £1,150 Superannuation under the F S S U Family allowances

Application forms and further particulars may be obtained from the Registrar of the College, Manchester, 1, to whom completed applications should be returned not later than Saturday November 2, 1963

UNIVERSITY OF ABERDEEN

DEPARTMENT OF BOTANY

Applications are invited for the post of Lecturer or Assistant Lecturer in Botany Preference will be given to applicants whose interests lie in the field of cytology or cytogenetics The appointee will be expected to take up his duties by October, 1964 or sooner if possible Salary on scale Lecturer, £1,250 to £2,150 , Assistant Lecturer, £1,000 to £1,150, all with placing according to qualifications and experience F S S U , child allowance and removal allowance

Further information and forms of application may be obtained from the Secretary, the University, Aberdeen, with whom applications (eight copies Lecturer, two copies Assistant Lecturer), should be lodged not later than November 18 1963

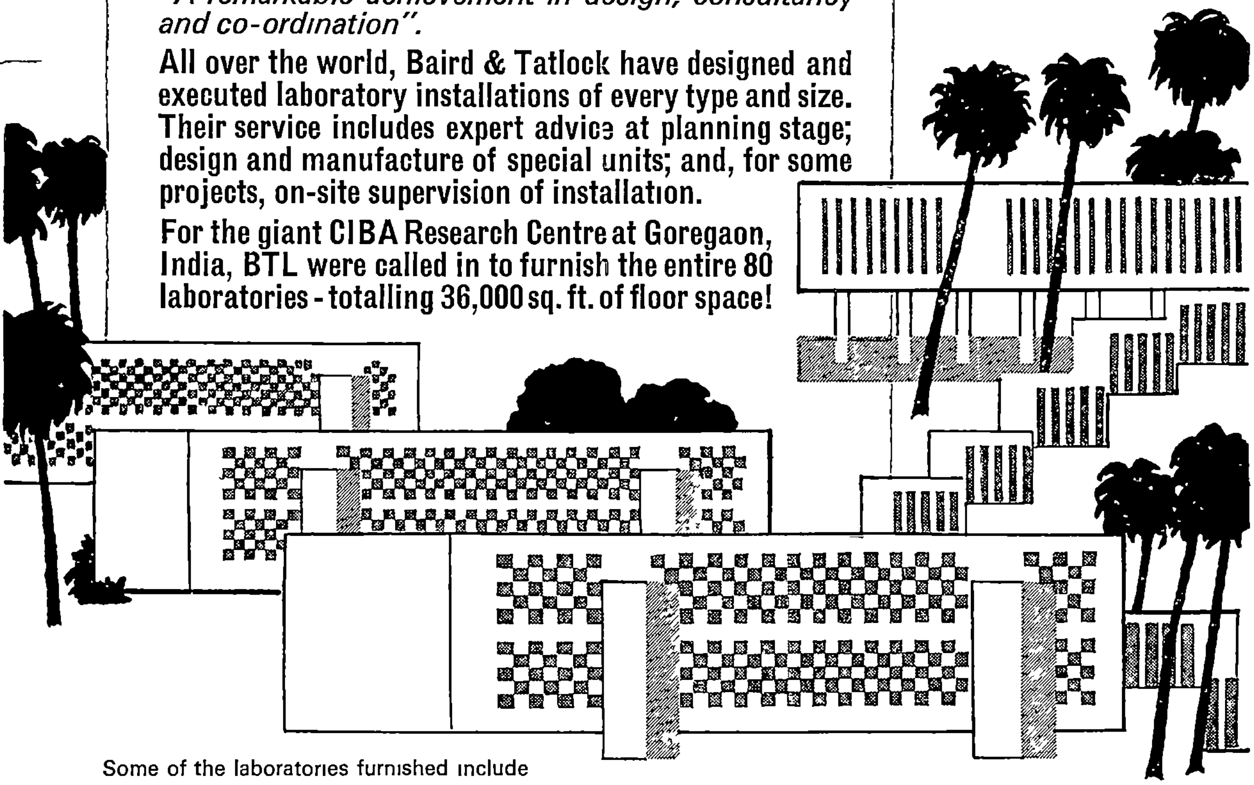
COMPLETELY FURNISH THE
LABORATORIES OF SOUTH ASIA'S
LARGEST RESEARCH CENTRE!

"A remarkable achievement in design, consultancy and co-ordination".

All over the world, Baird & Tatlock have designed and executed laboratory installations of every type and size. Their service includes expert advice at planning stage; design and manufacture of special units; and, for some projects, on-site supervision of installation.

For the giant CIBA Research Centre at Goregaon, India, BTL were called in to furnish the entire 80 laboratories - totalling 36,000 sq. ft. of floor space!



Some of the laboratories furnished include
Textile Preparation & Dyestuffs Laboratories Analytical laboratories Balance Room Polarimeter labs Optical Methods labs Electronic Workshop Precision Machine shop Apparatus Room **Pharmaceutical Laboratories** General Laboratories Distillation & Extraction labs Tracer labs Paper Chromatography labs Pharmacological labs · Parasitology labs Bacteriology labs Hydrogenation laboratory

The installation included 2950 ft. of benching and 34 specially designed fume-cupboards with balanced draught systems Pre-serviced racks were shipped from England ready for installation and the manufacture of all timber work in India was closely supervised by BTL's design consultants, who, at all stages of the project worked in very close liaison with CIBA and their architects –the internationally known firm of Suter & Suter.

Wherever you are extending existing facilities, or planning a complete new laboratory – call in the BTL Furnishings Division! This is the first step towards the speedy and successful completion of your laboratory project
